## Lines

- **Line positions** provide information about the gas composition (identification), as well as about its dynamics (redshifts, gas outflows)
- **Line intensities** provide information about the column of the absorbing material (including ions), constrains on the ionization degree of the gas ( $\xi = L/nR^2$ ), temperature and density
- **Line shapes** provide information about the thermal and turbulent motions of the gas, and can also probe relativistic effects near strong gravitational fields

Liedahl+Torres05

The X-ray band ( $\sim 0.1 - 10$  keV) covers the emission and absorption produced by the inner-shell transitions of the astrophysically abundant ions ( $C \rightarrow Ni$ ).

# X-ray Emission Lines

for a multi-electron atom

# Astrophysical Plasmas

In general, there are two types of X-ray emitting plasmas

**Collisional:**

$kT \sim$  Ionization energy of the ions in the plasma

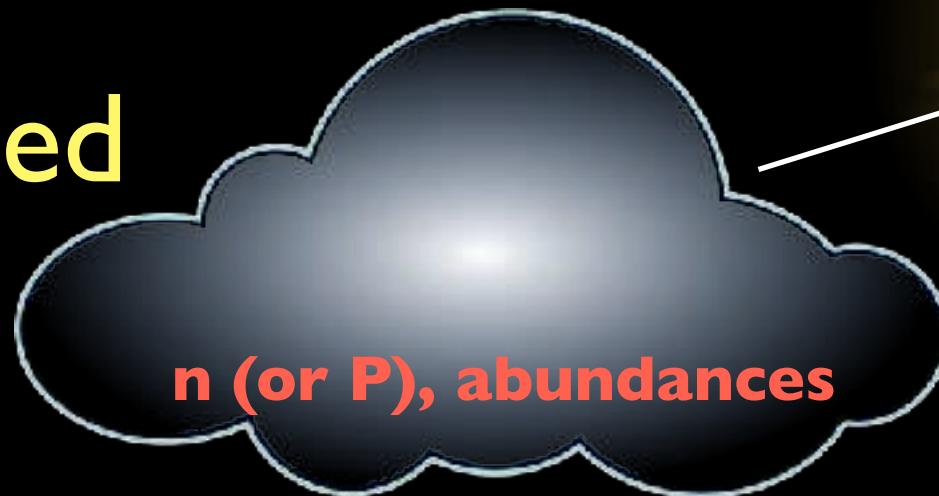

**Photoionized:**

$kT \ll$  Ionization energy of the ions in the plasma

# Collisional

# Photoionized

**T is not a free parameter!**

# Collisional Plasmas

$kT \sim$  Ionization energy of the ions in the plasma

## Collisional Radiative:

$$N_e = 10^{14} - 10^{27} \text{ cm}^{-3}$$

Collisions compete with photons in de-exciting levels. A level with a small A value may be collisionally de-excited before it can radiate

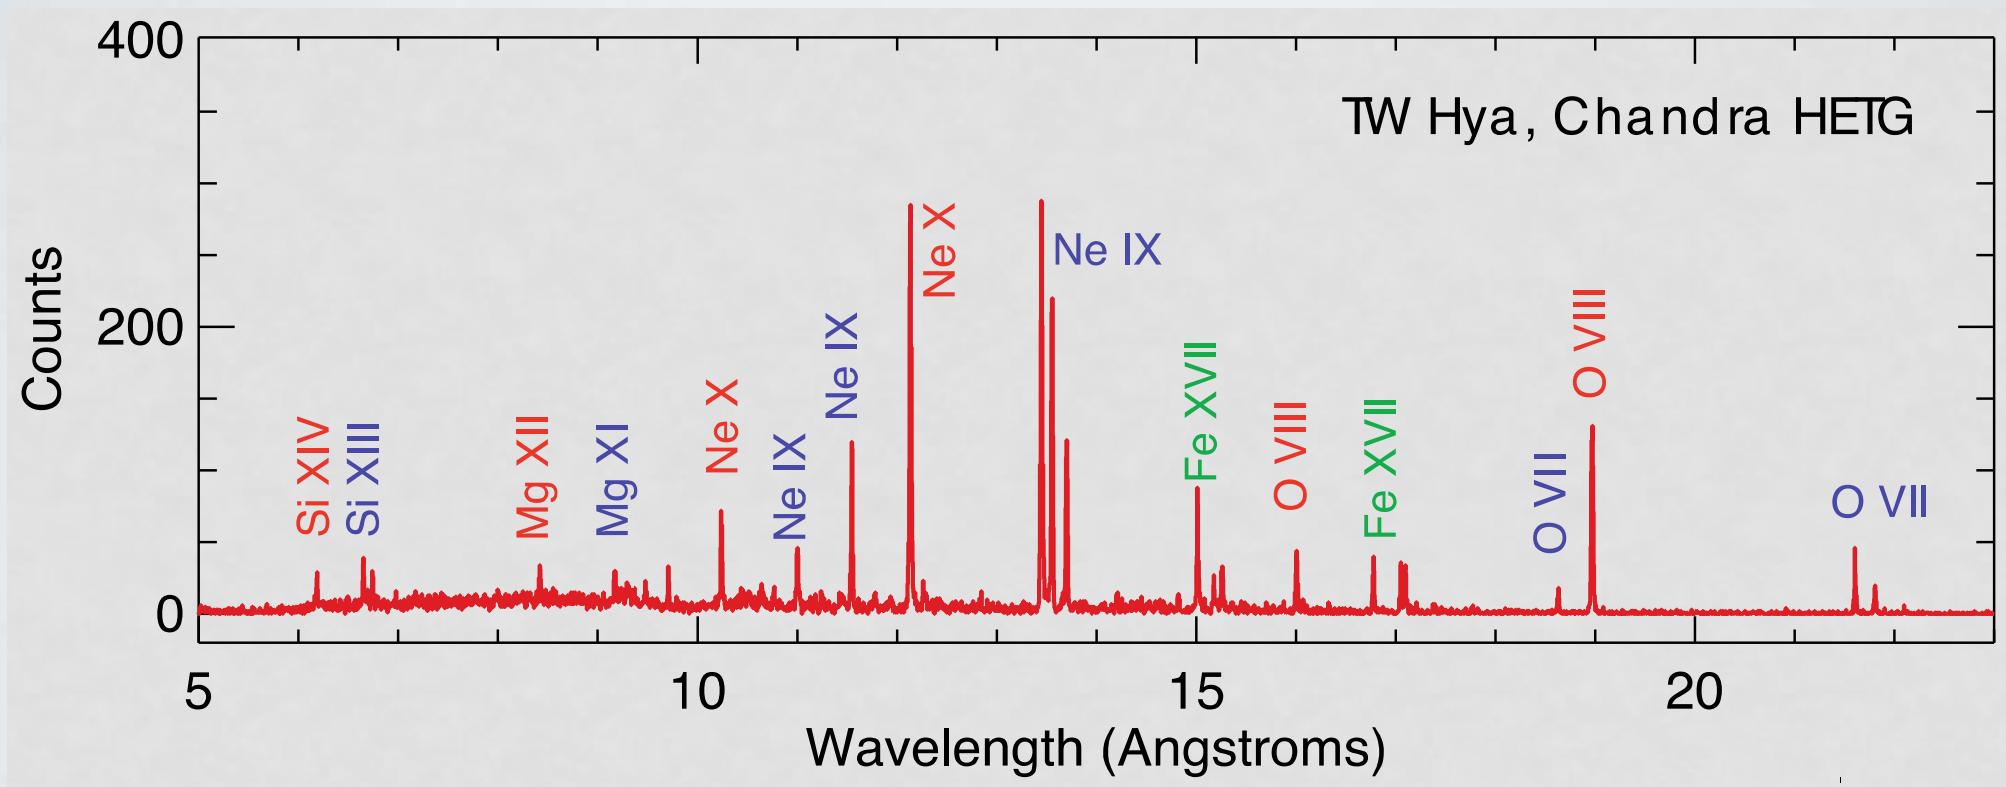

## Coronal/Nebular:

$$N_e < 10^{14} - 10^{16} \text{ cm}^{-3}$$

In a Coronal plasma, collisions excite ions but are too rare to de-excite them; decays are purely radiative. This is also called the “ground-state” approximation, as all ions are assumed to be in the ground-state when collisions occur.

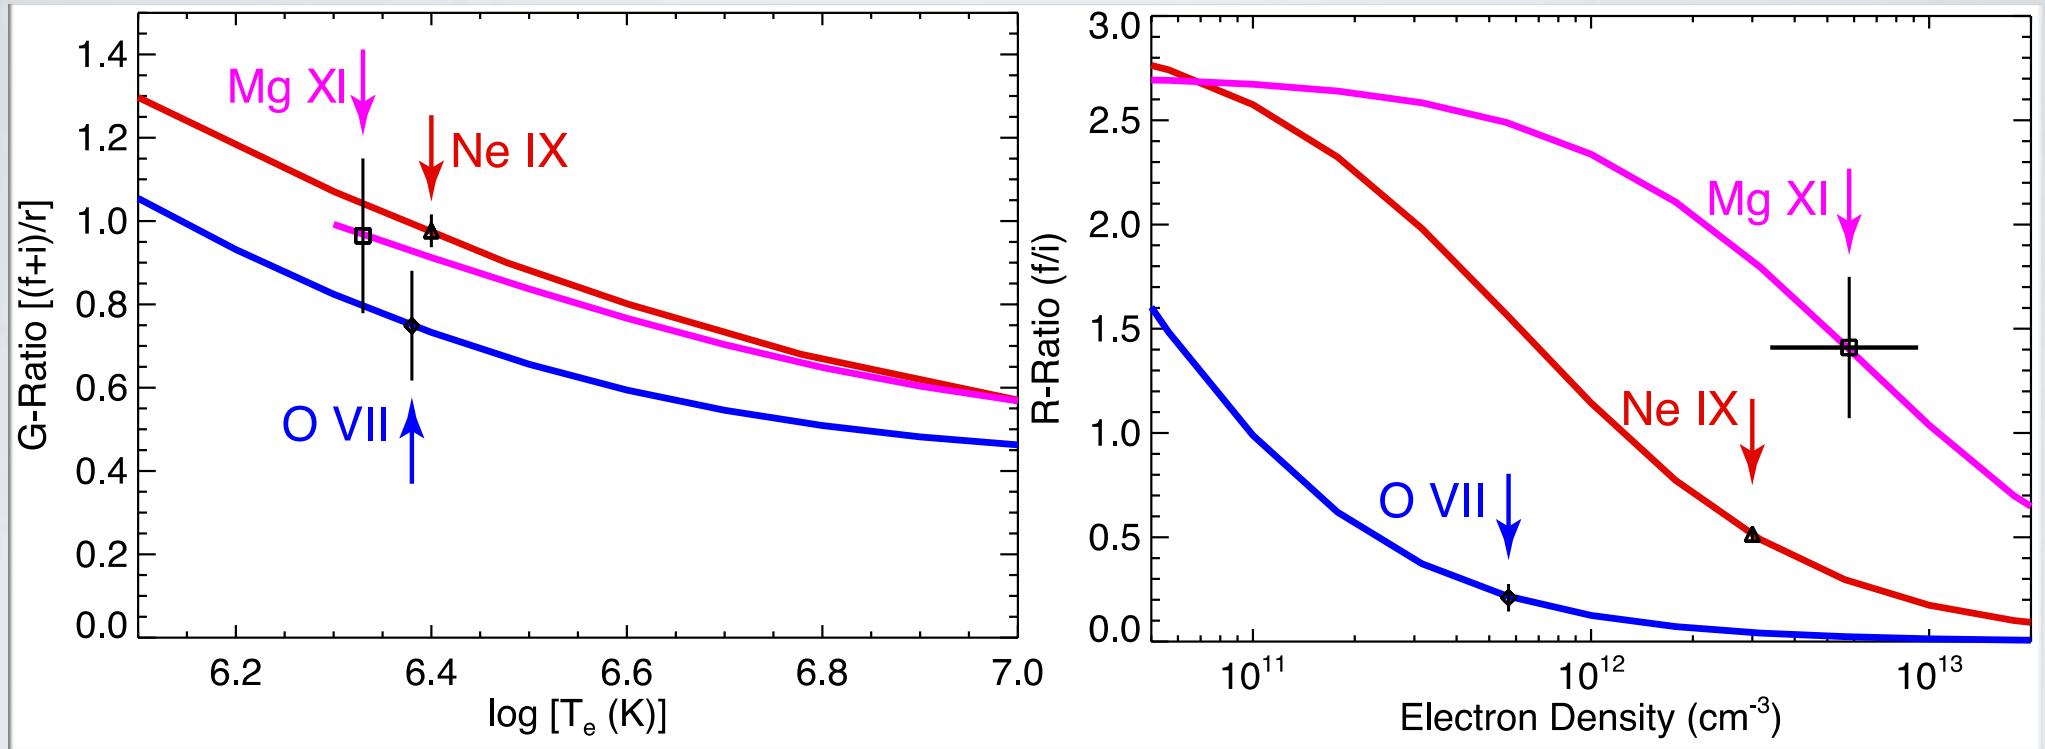

# Collisional Plasmas

HETG ~500 ks Chandra observation of the accreting young star  
TW Hydrea (Brickhouse et al 2010)

Spectrum dominated by H- and He-like emission lines

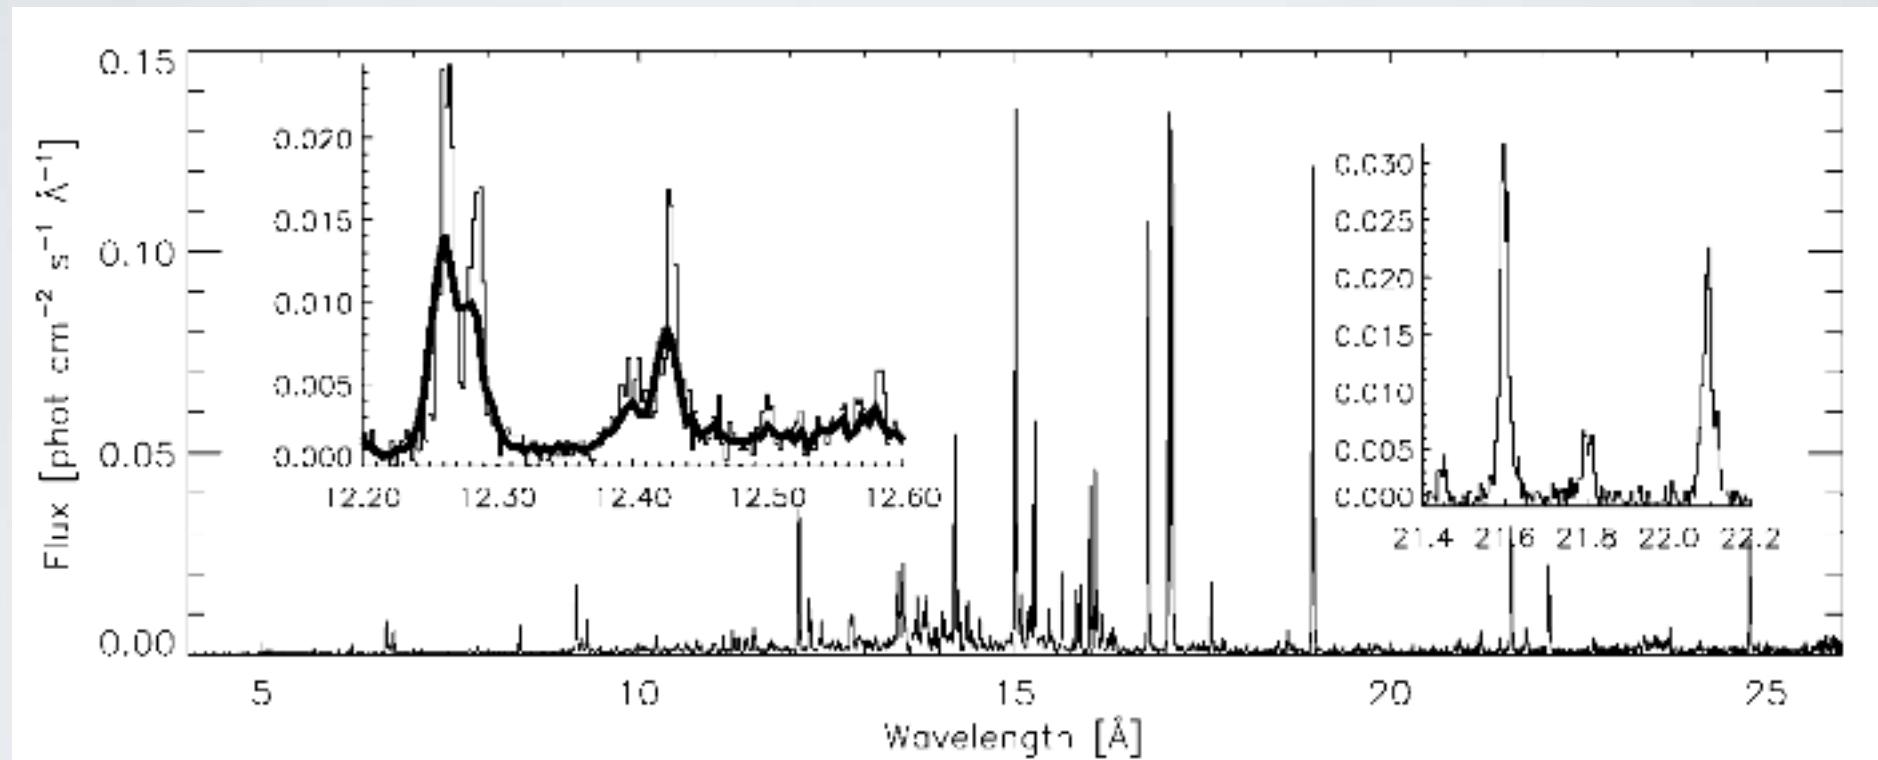

# Collisional Plasmas

While the **temperature** diagnostics for Mg XI, Ne IX, and O VII all give roughly the same result, the **density** diagnostics are quite different, especially for O VII, leading to the primary result.

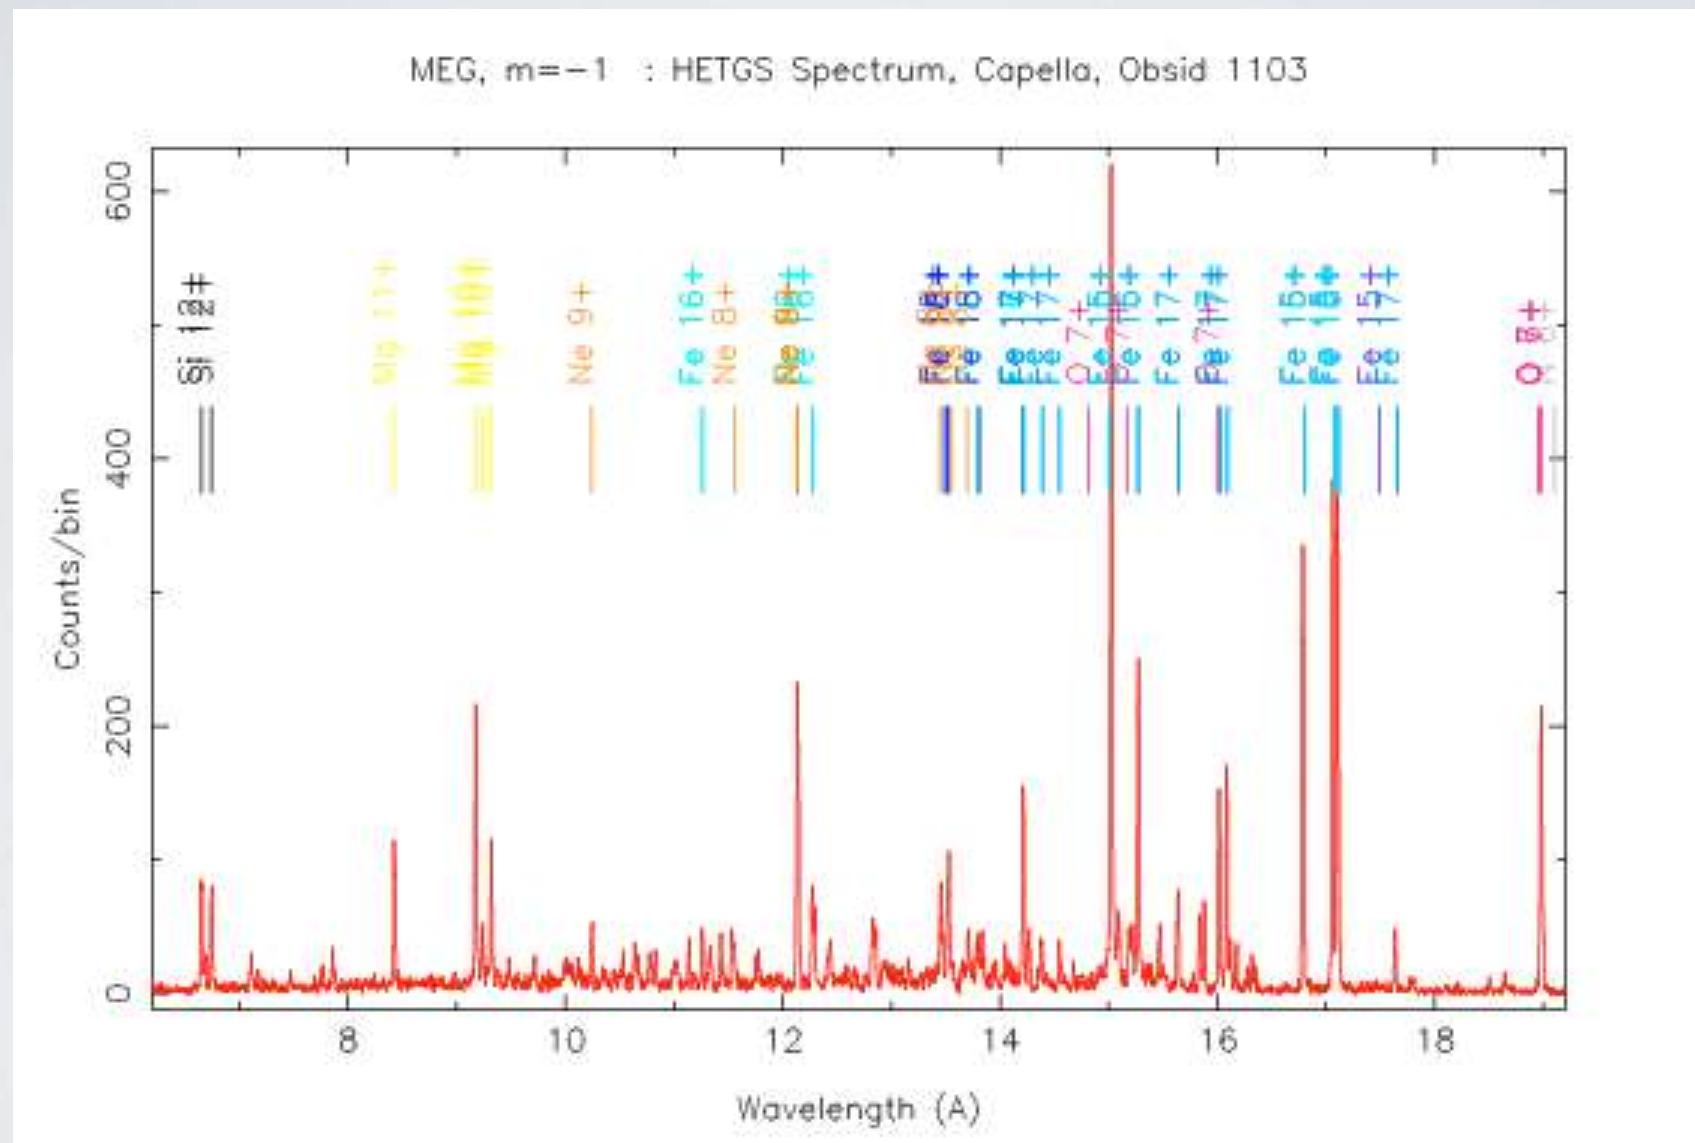

# Coronal Plasmas

Capella: Active binary system (G1 and G8 giants) with a rich spectrum of X-ray emission lines

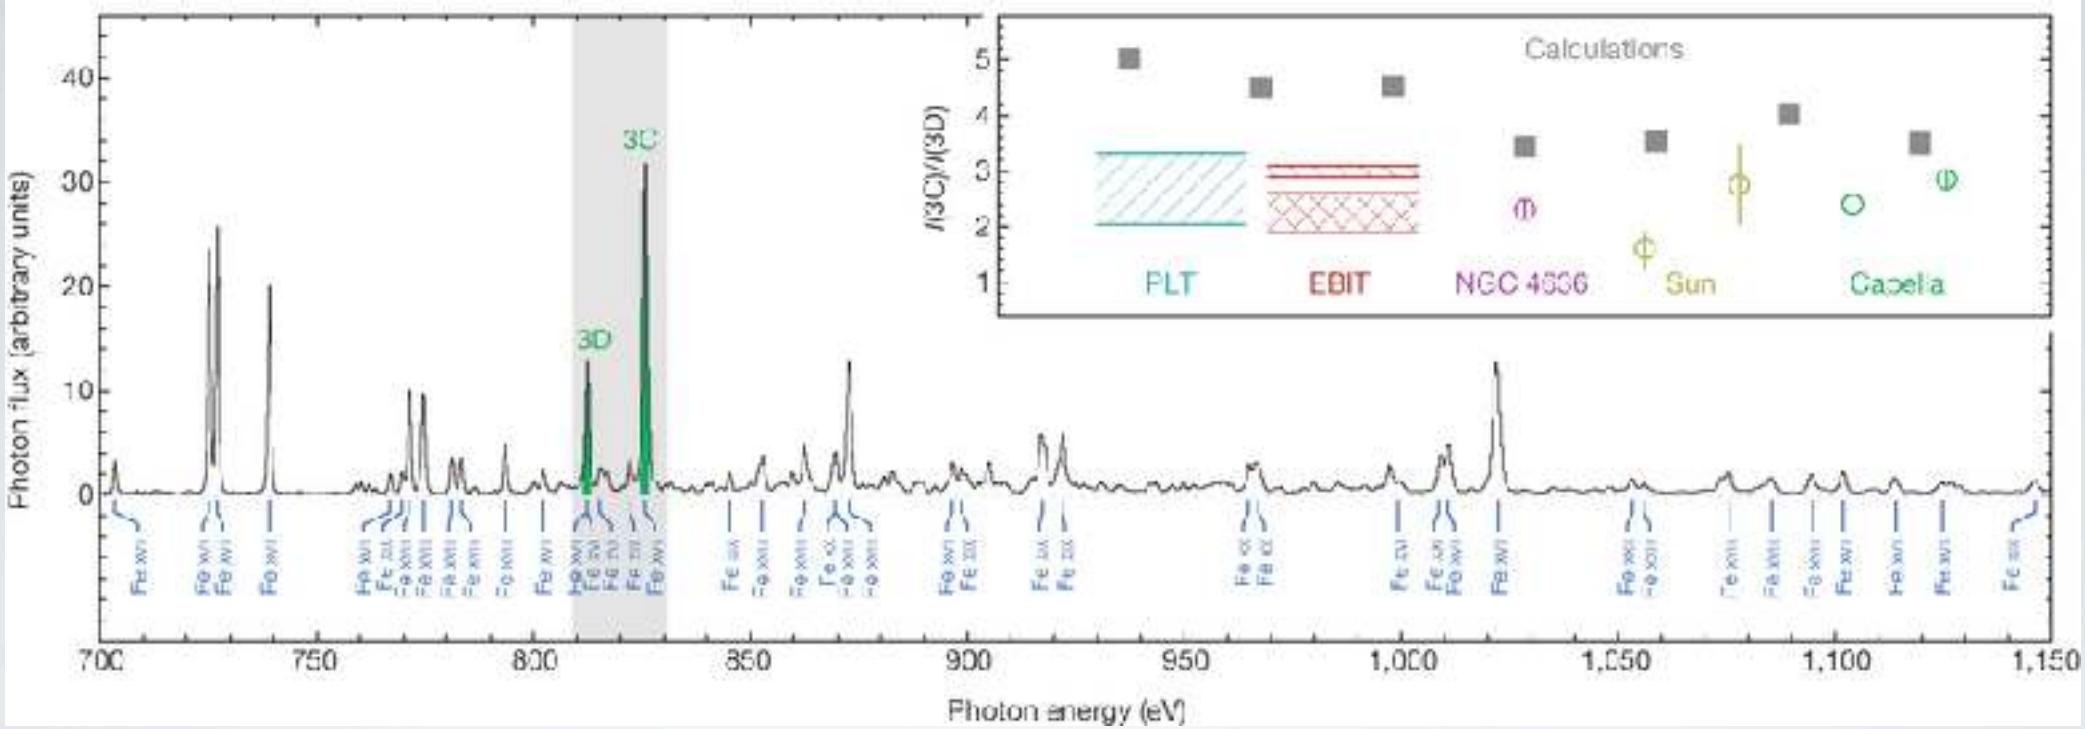

89 ksec Chandra HETG (Canizares et al. 2000)

# X-ray Emission from Capella

# Coronal Lines Testing Atomic Data

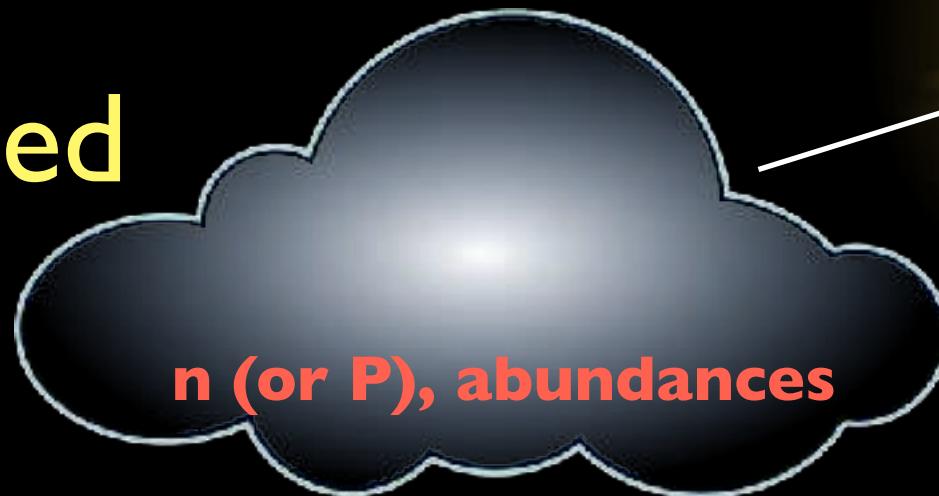

An unexpectedly low oscillator strength compared to the theoretical calculations has been proposed as the origin of the Fe XVII emission problem (Bennitt et al. 2012)

# Collisional

# Photoionized

**T is not a free parameter!**

# Photoionized Plasmas

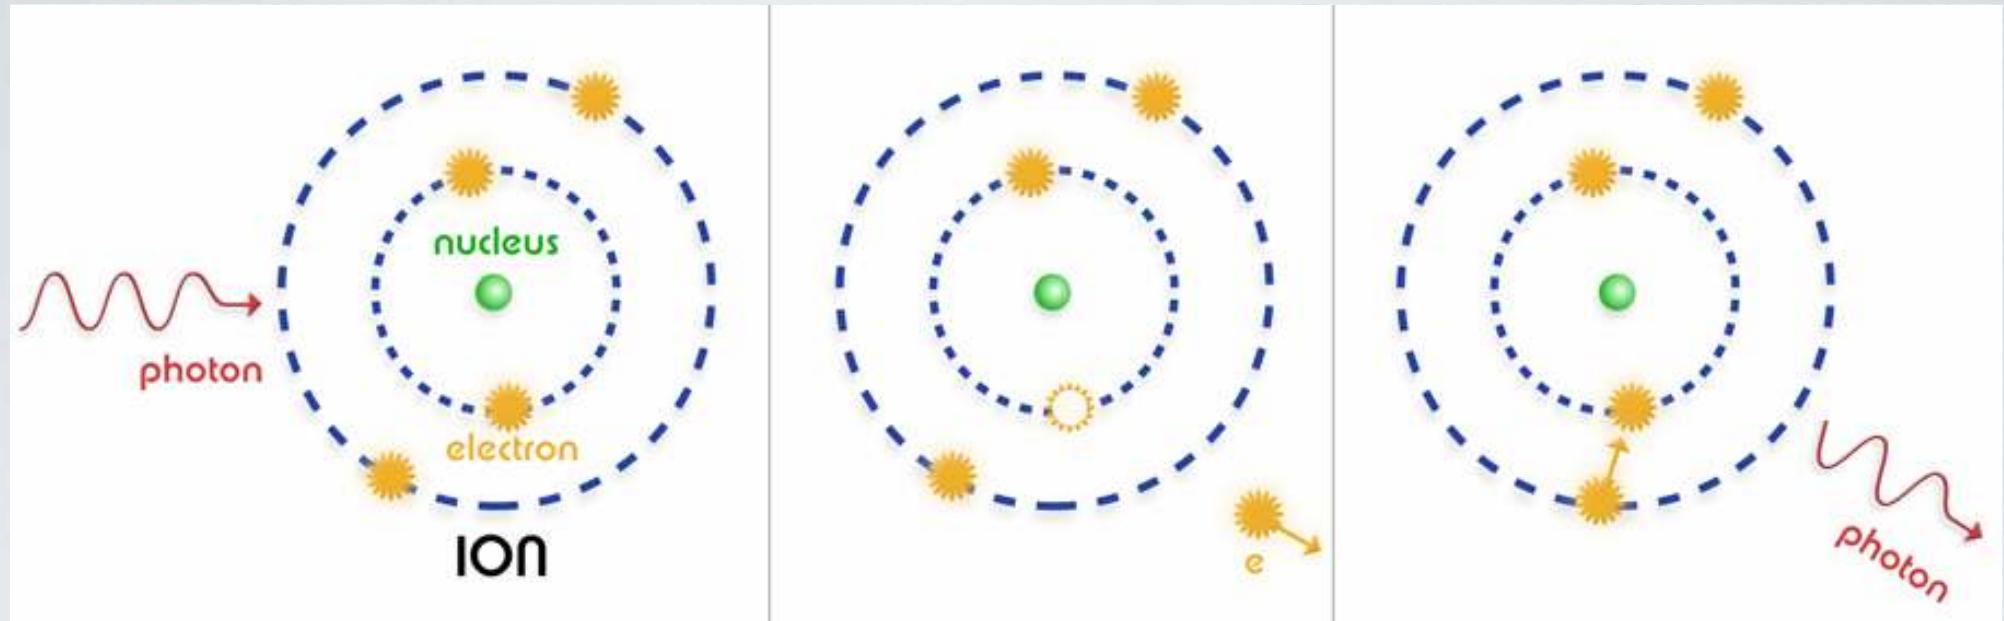

- Photoionization of plasmas occurs when an external source of radiation illuminates a relatively cold material
- Incident photons excite and/or ionize atoms in the gas
- The gas is heated by photo-absorption or scattering of photons by cold electrons
- Cooling is achieved by both continuum and line emission
- In a photoionized gas, equilibrium is reached at a particular temperature where heating balances cooling

Therefore, the gas **temperature** needs to be calculated self-consistently, and the **ionization balance** is determined by the strength and shape of the incident radiation (for a given density or pressure)

# Photoionized Plasmas

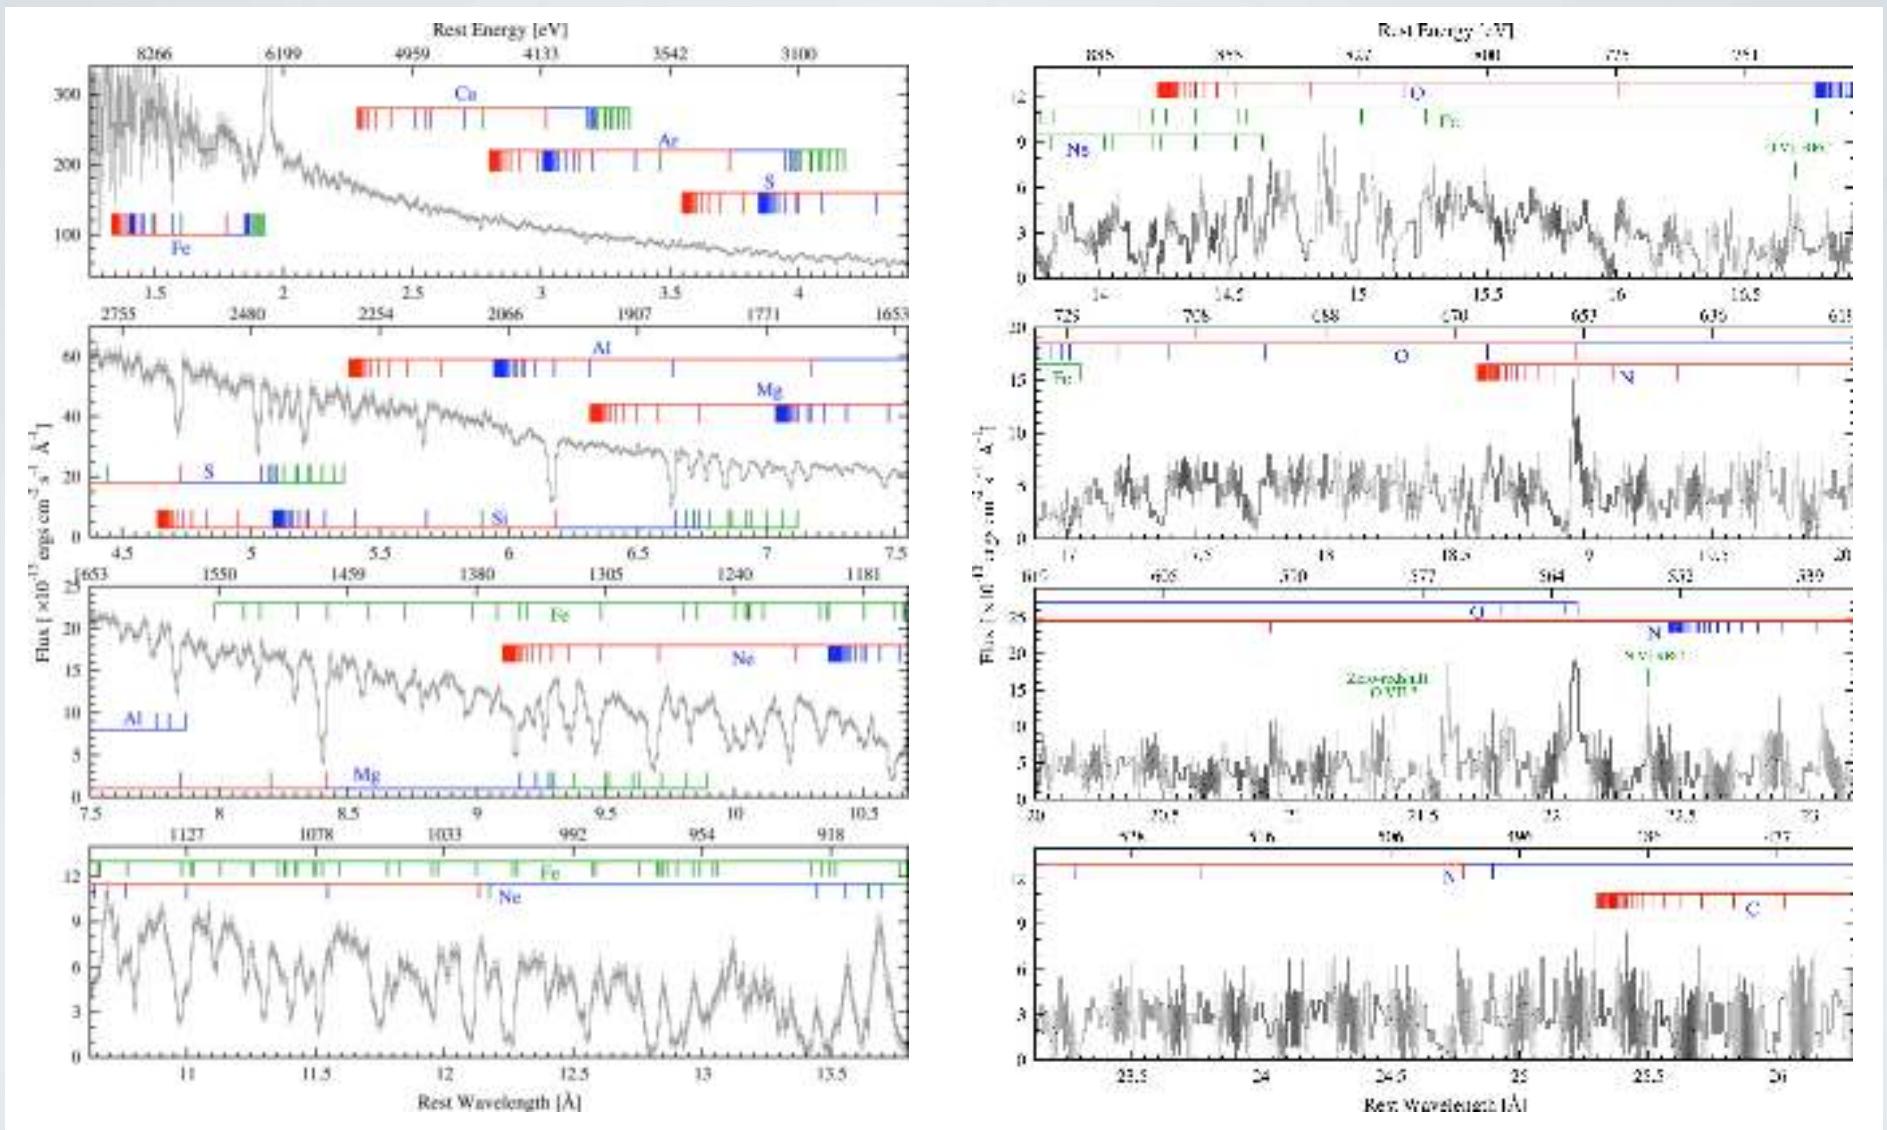

- Ionization balance allows for the possibility of different ionic species to co-exist with similar abundances
- Complex emergent spectrum:
  - Absorption: continuous (photoelectric); discrete (lines, resonances and edges)
  - Emission: continuous (thermal black-body, bremsstrahlung); discrete (fluorescence lines, radiative recombination continua)
- **Inner-shell** ionization and fluorescence emission particularly important for X-ray astrophysics

# K-shell Fluorescence

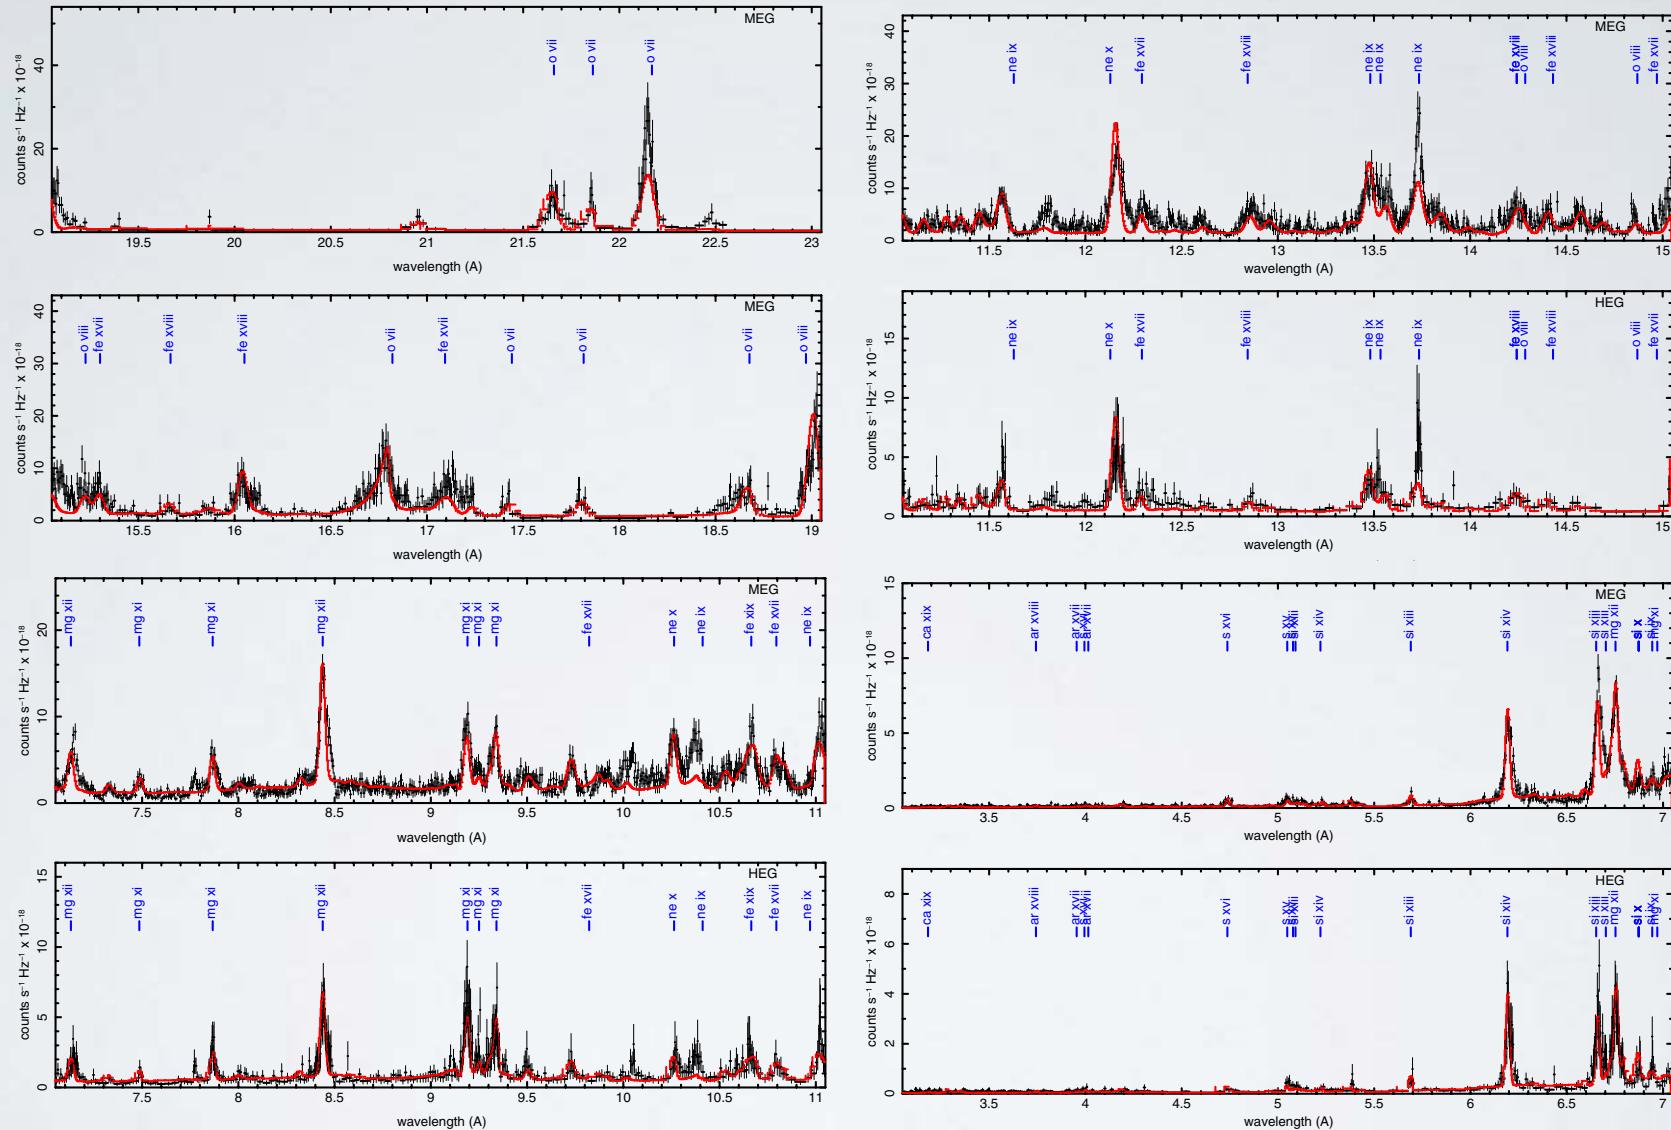

- Needs L-shell electrons
- Photoionization, then either  $2p \rightarrow 1s$  radiative transition or Auger ionization
- Fluorescence yield  $\sim Z^4$ , appreciable for a high-Z element
- Such a process is an important contributor to iron K emission

# Photoionized Plasmas

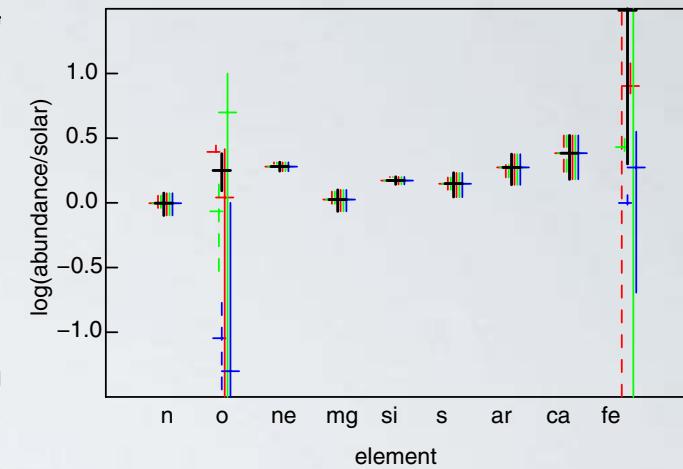

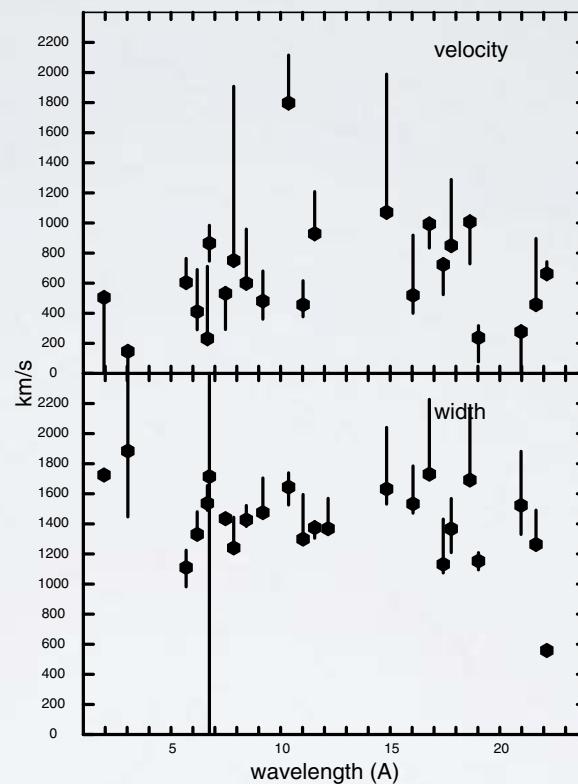

NGC 3783 900 ksec Chandra observation, over 135 lines identified!  
Kaspi et al (2003)

# Photoionized Gas in NGC 1068

Fits of the **XSTAR** model to 400 ksec Chandra HETG observation  
(Kallman et al. 2014)

# Photoionized Gas in NGC 1068

Kallman et al. (2014)

- H-like and He-like ions from C to Si, as well as significant emission due to Fe L-shell transitions
- Bright RRC point to the predominance of recombination in a photoionized plasma
- Diversity of ionization parameters ranging from  $\xi \sim F_x/n_e = 10$  to 1000.

# Plasma Codes

Understanding a plasma requires a physical model. For these, a large number of atomic lines are needed (hundreds or more). Modern plasma codes have made of the hard work, compiling millions of transitions!

# Summary

Although moderately complex, there are relatively few processes that dominate X-ray emission; analyzing the observed spectrum from each can reveal the underlying parameters. These processes are:

- Line emission
  - **Collisional**  $\Rightarrow$  temperature, abundance, density
  - **Photoionized**  $\Rightarrow$  ionization state, abundance, density
- Synchrotron emission  $\Rightarrow$  relativistic electrons, magnetic field
- Inverse Compton scattering  $\Rightarrow$  relativistic electrons
- Blackbody  $\Rightarrow$  temperature, size of emitting region / distance<sup>2</sup>
- Absorption  $\Rightarrow$  abundance, density, velocity

# Einstein and the Space-Time

*The Persistence of Memory*, by Salvador Dali

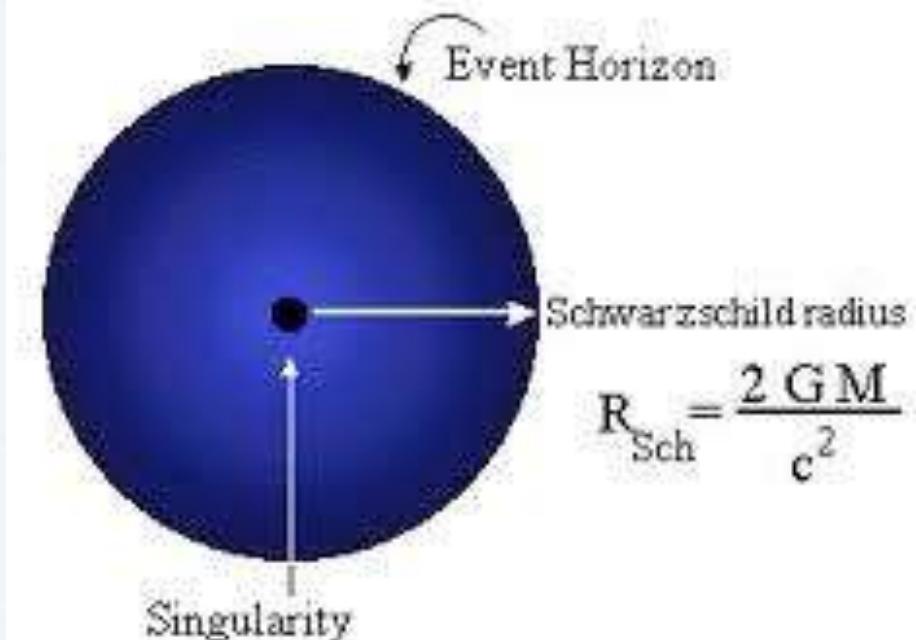

# Theoretical prediction of Black Holes

In 1915, provided the first exact solution to the Einstein field equations of general relativity (for non-rotating mass).

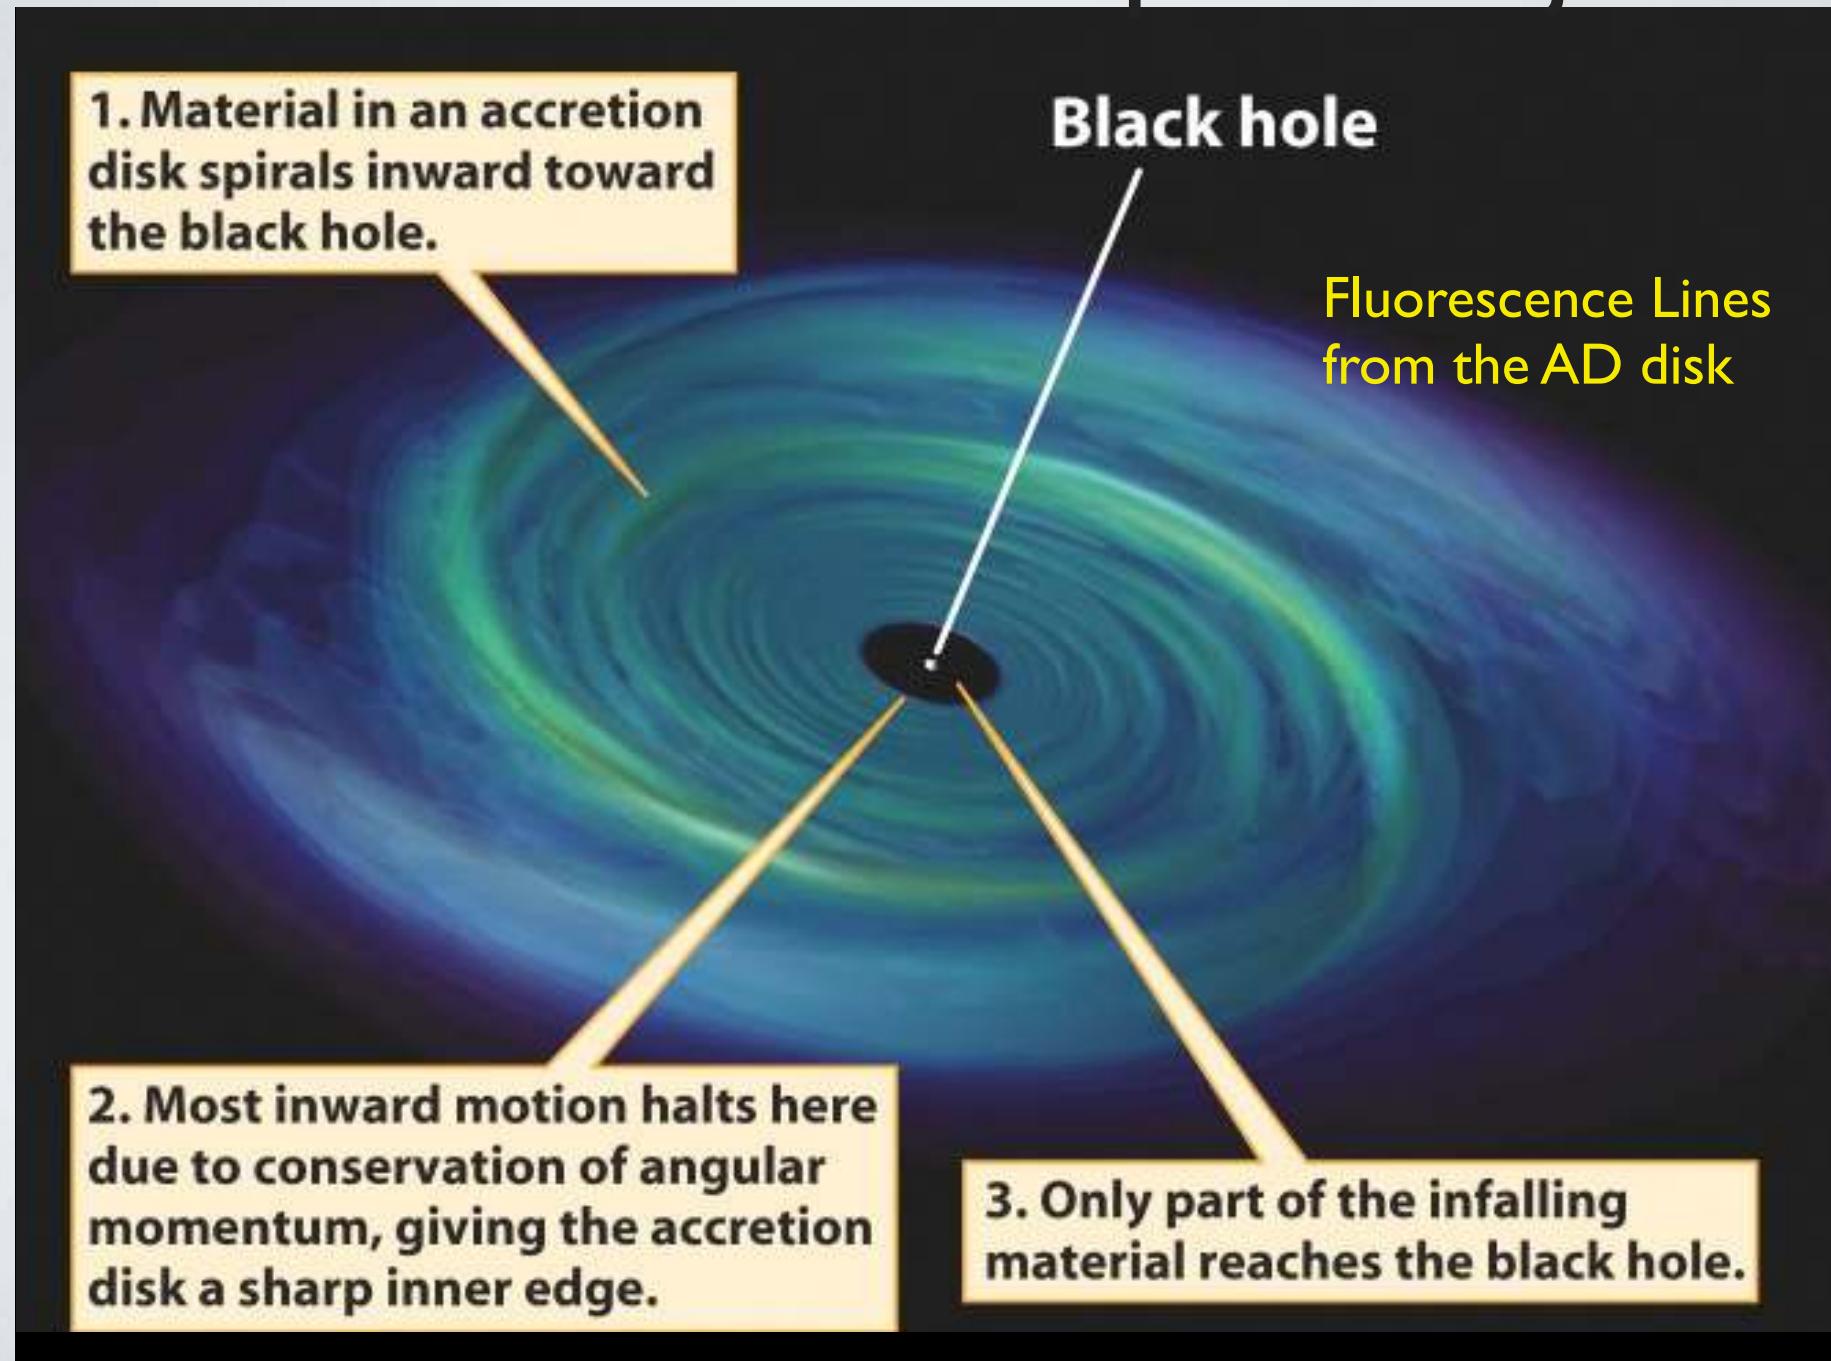

"As you see, the war treated me kindly enough, in spite of the heavy gunfire, to allow me to get away from it all and take this walk in the land of your ideas."

- Schwarzschild to Einstein, December 1915.

$$R_{\text{Sch}} = \frac{2GM}{c^2}$$

# X-ray Reflection First Detections

**1960-1970's:** First X-ray observatories were launched: *Uhuru, Ariel-V, OSO-8, HEAO-1*.

Several X-ray sources were associated with AGN, with a power-law continuum with Gamma  $\sim 1.7$  (e.g., Tucker et al. 1973; Mushotzky, 1976, 1984).

Ginga Observation of NGC 5548 showing one of the first clear detection of Fe K emission near 6.4 keV (Pounds et al. 1989)

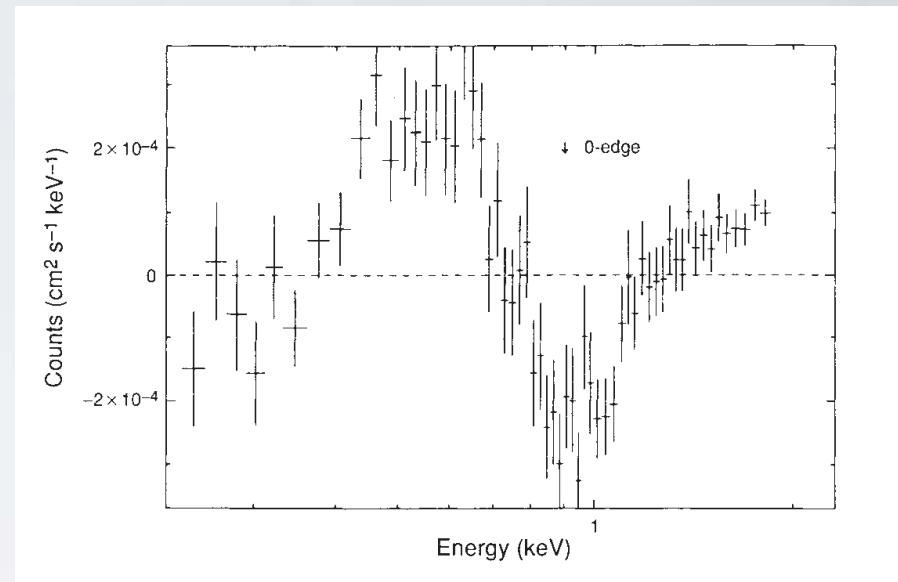

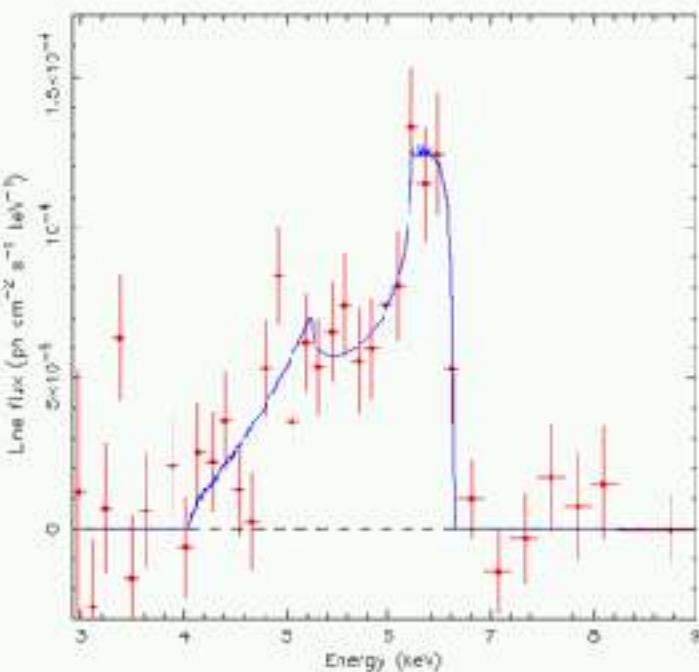

UHURU Observation of NGC 5128 (Tucker et al. 1973)

**1980's: Einstein, EXOSTAT, Tenma, Ginga.**

Detection of Fe K emission and absorption as a common property of Seyfert galaxies (Pounds et al. 1989, 1990; Matsuoka et al. 1990; Nandra & Pounds 1994).

# X-ray Reflection First Detections

**1990's:** ROSAT, ASCA. First CCDs flying on X-ray observatories. First detections of a distorted Fe K line, which was interpreted as emission affected by relativistic effects near the BH (Tanaka et al. 1995; Nandra et al. 1997; Fabian et al. 2000).

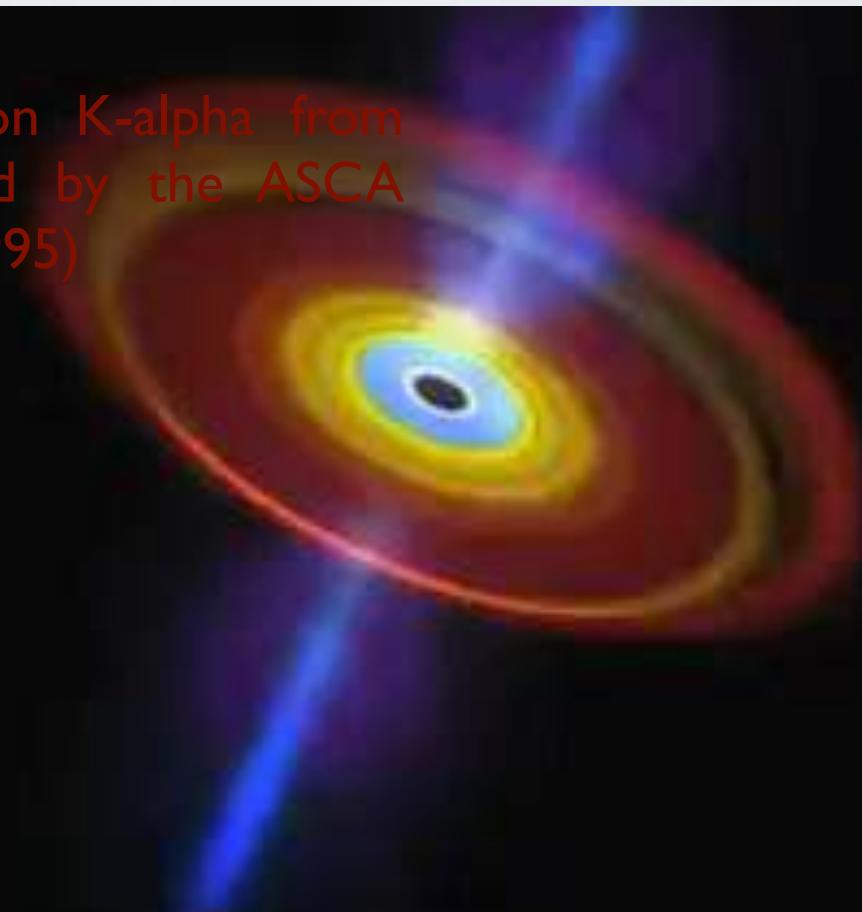

Residuals from a power-law fit to the ROSAT spectrum of MCG-6-30-15, showing a strong absorption feature at  $\sim 0.8$  keV due to iron.

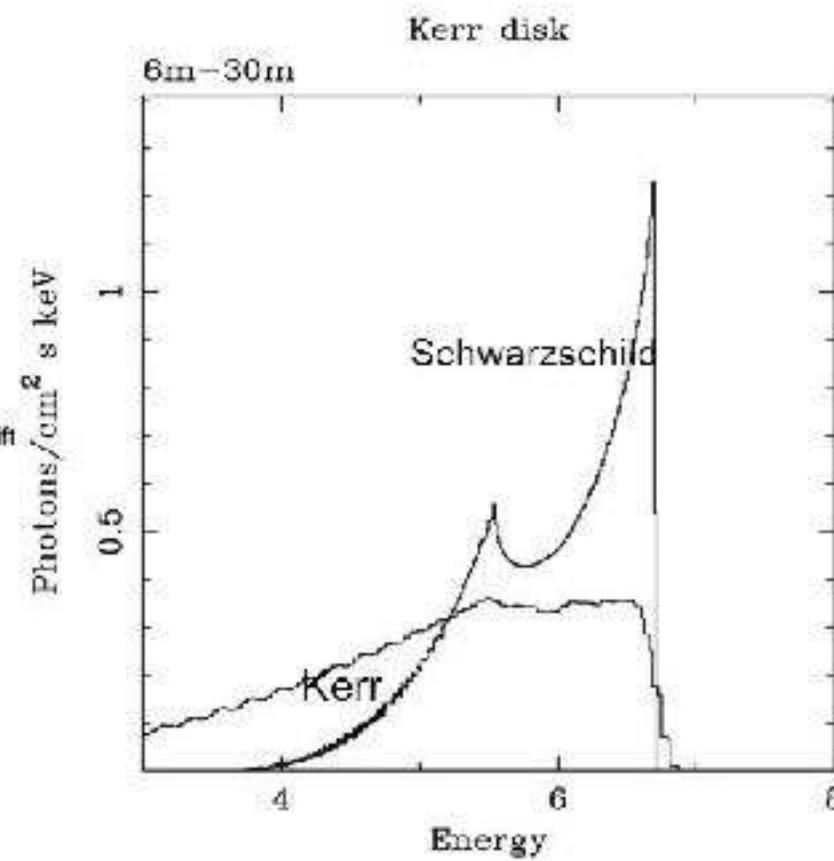

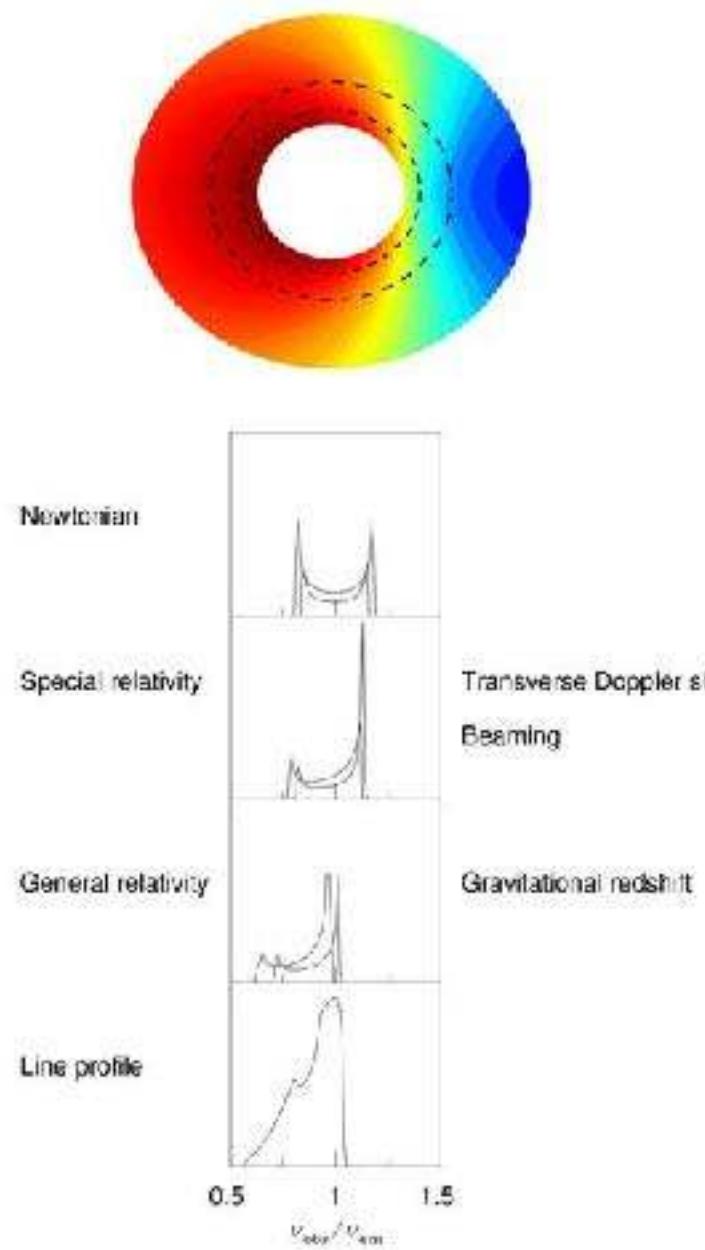

The line profile of iron K-alpha from MCG-6-30-15 observed by the ASCA satellite (Tanaka et al. 1995)

# X-ray Reflection from the Inner-Disk

The line profile of iron K-alpha from MCG-6-30-15 observed by the ASCA satellite (Tanaka et al. 1995)

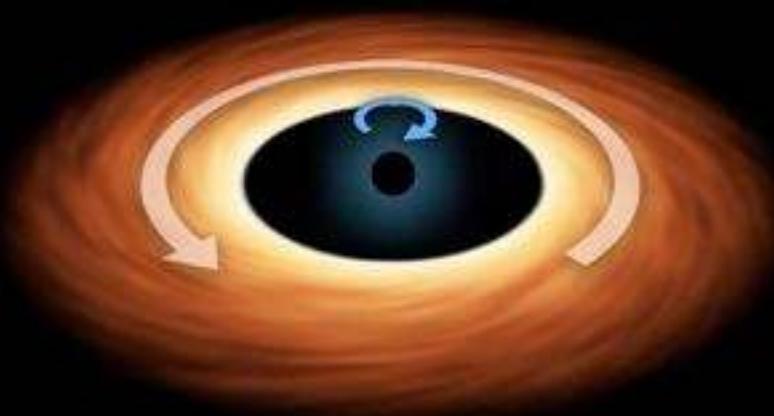

# Relativistic Effects (Special + General)

# Neutral & Distant Reflection

- \* **PEXRAV** (Magdziarz & Zdziarski)
- \* **PEXMON** (Nandra)

Provide very simplistic calculation of the reflection spectra.  
No geometrical information.

- \* **TORUS** (Brightman & Nandra)
- \* **MYTORUS** (Murphy & Yaqoob)

Provide very simplistic calculation of the reflection spectra,  
but good geometrical information

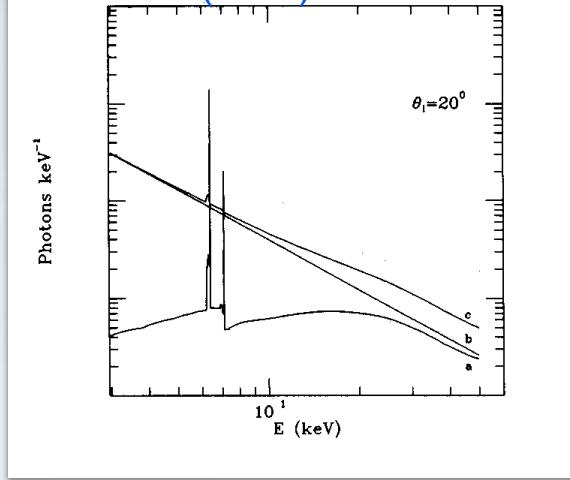

- \* **REFLIONX** (Ross & Fabian)
- \* **XILLVER** (Garcia & Kallman)

Provide detailed calculations of the reflection spectra (also  
including ionization). No geometrical information.

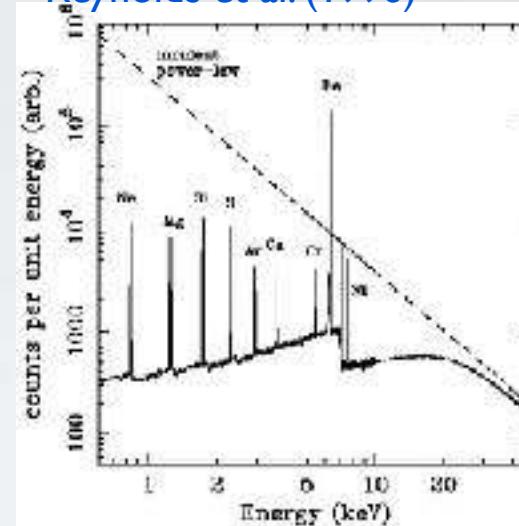

# X-ray Reflection from Cold Material

Reflection modeling is being around for a long time...

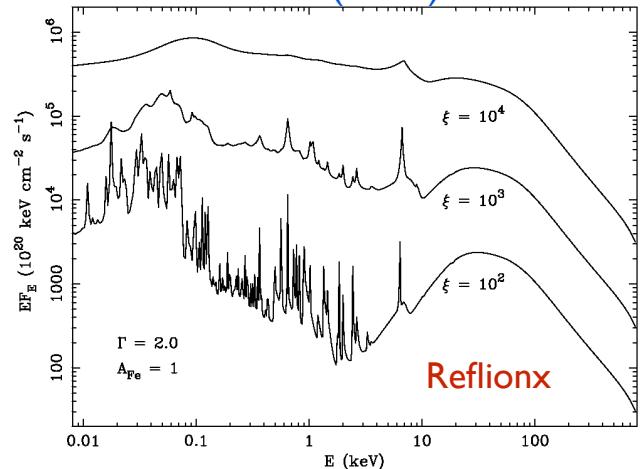

Matt et al. (1991)

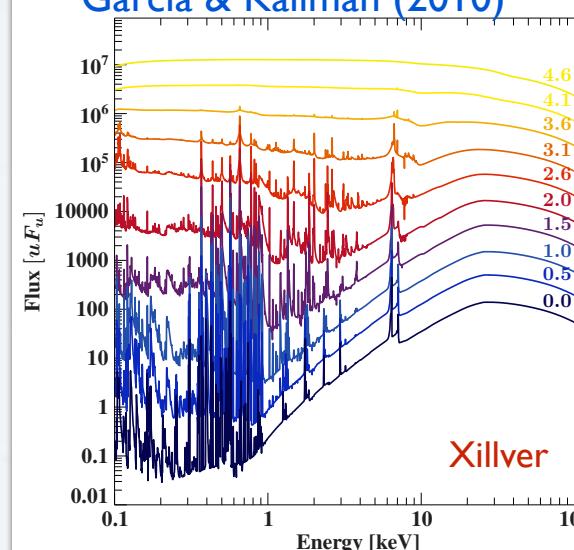

Reynolds et al. (1996)

Ross & Fabian (2005)

García & Kallman (2010)

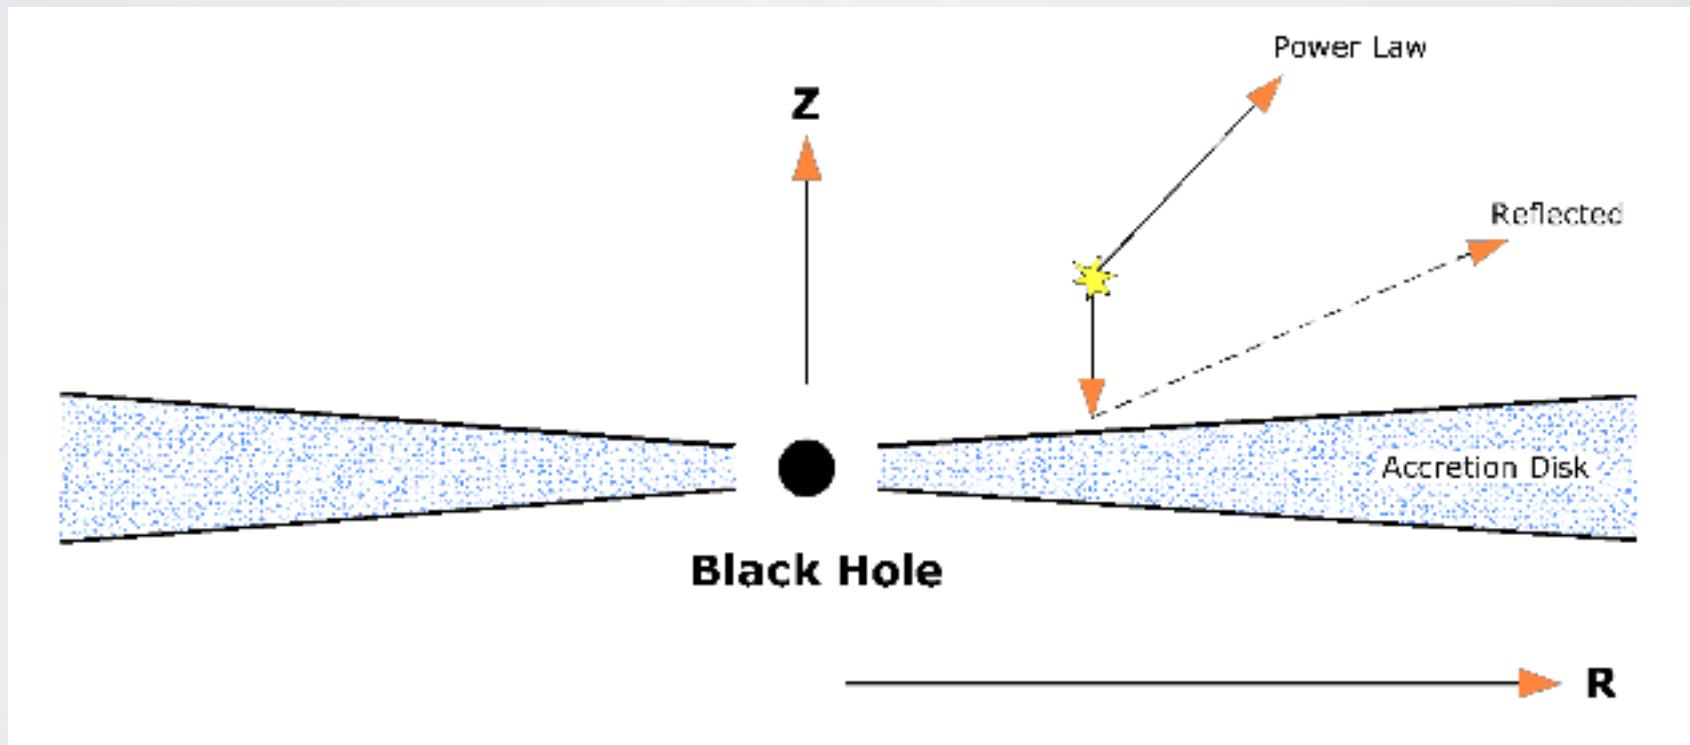

Current models allow for ionization structure (thus, not so cold material)

# Calculation of the Reflected Spectrum

Simplistic assumptions regarding the geometry of the system:

- The illumination is prescribed
- The calculation is done at one single place in the disk
- Gas density is constant in the vertical direction
- No magnetic fields

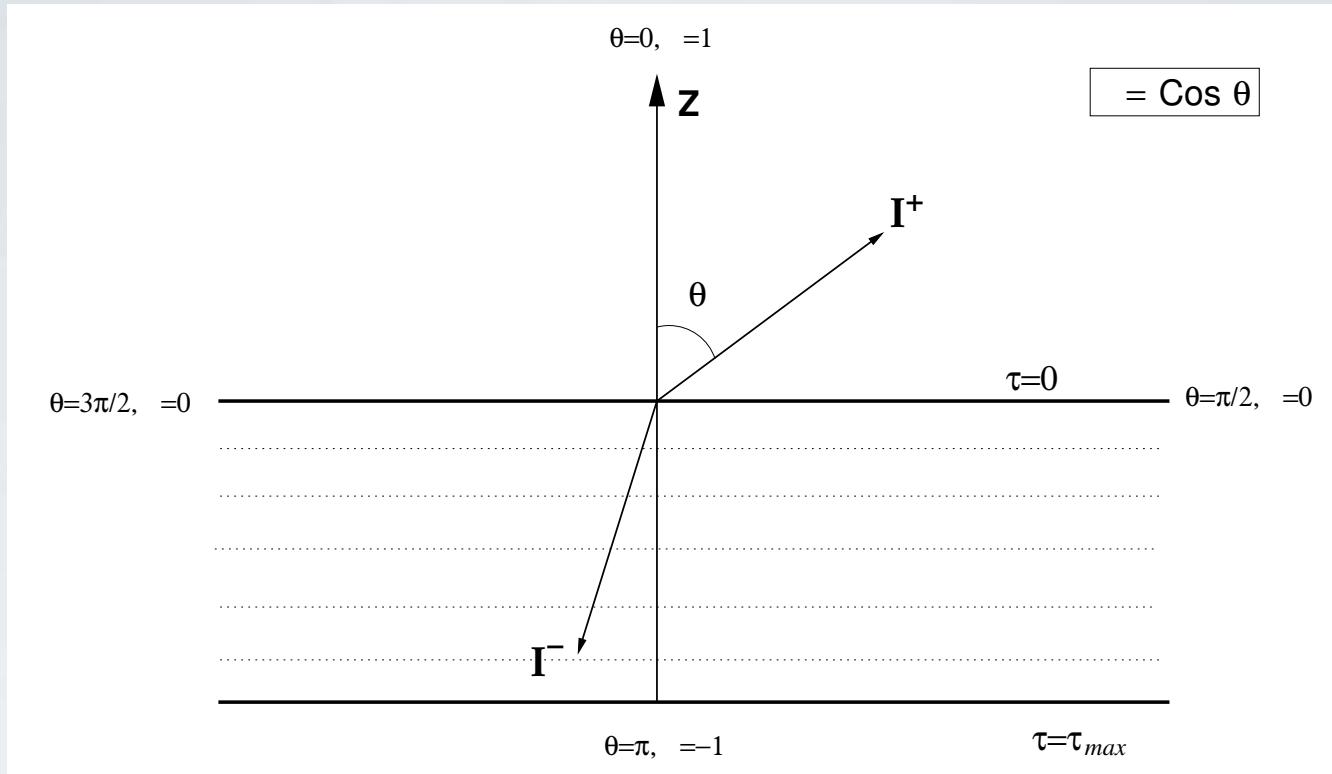

# Ionized Reflection in a Nutshell

In any photo ionized plasma, one needs to solve at least 3 basic equations:

- 1) Level Populations: All processes populating an atomic level are balanced by those depopulating it.
  - 2) Energy: All heating processes are balanced with the cooling processes
  - 3) Radiation Transport: Interaction of the incident radiation field with the matter in the gas.
- \* Incident photons excite and/or ionize atoms in the gas
  - \* The gas is heated by photo-absorption or scattering of photons by cold electrons
  - \* Cooling is achieved through both continuum and line emission
  - \* Equilibrium is reached at a particular temperature where **Heating = Cooling**
- 
- \* Thus, gas temperature needs to be calculated self-consistently, and the ionization balance is determined by the strength and shape of the radiation field.

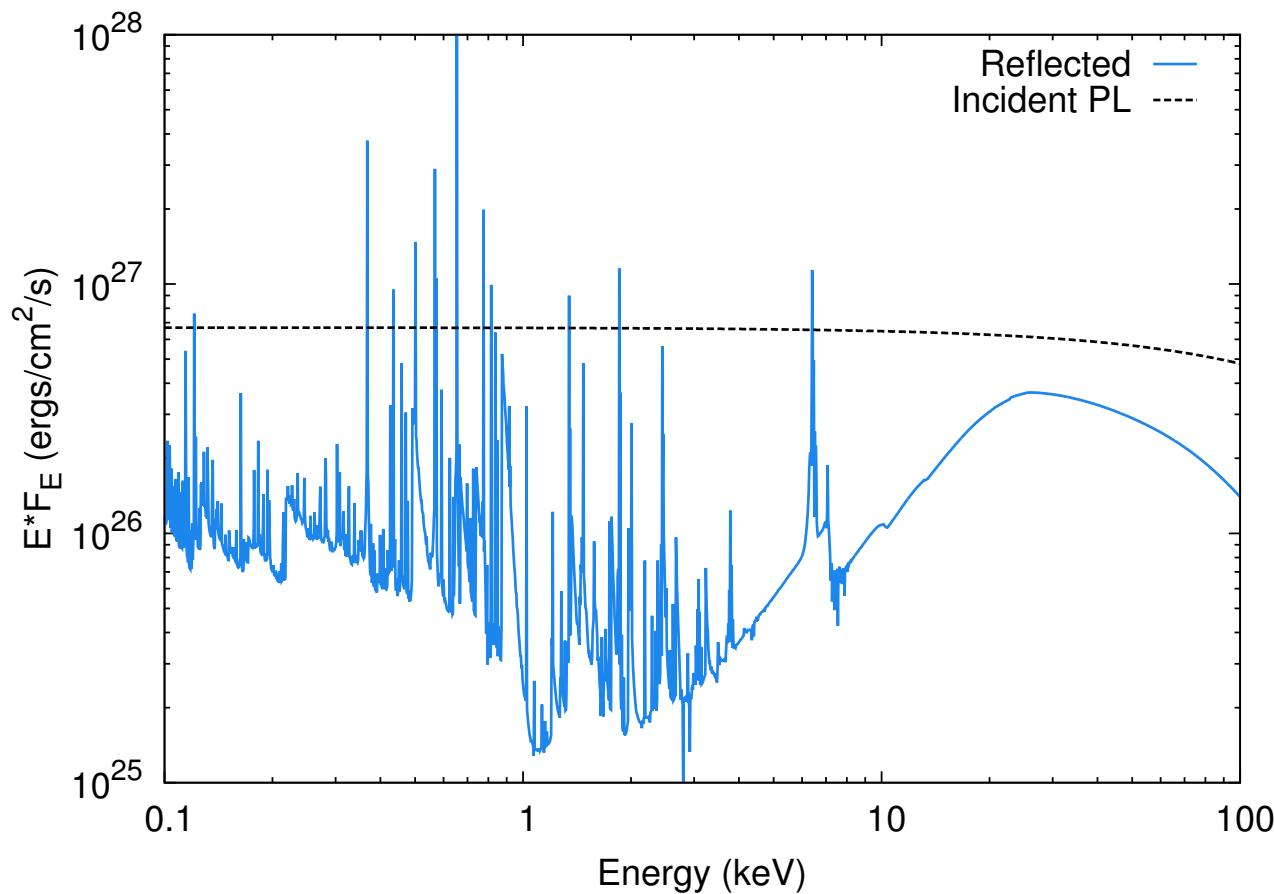

The result is a very complex emergent spectrum, with both absorption and emission features!

# The XILLVER Code for Ionized Reflection

- Solves the Radiation Transfer equation for every energy and angle at all depths, assuming plane-parallel geometry
- Solves the ionization balance using the XSTAR routines (Kallman & Bautista 2001)
- Includes the most complete and updated atomic data for inner-shell transitions
- Includes Comptonization of the radiation field within the disk

# XILLVER: Reflected Spectrum

Gamma=2, log Xi = 2, Afe = 1

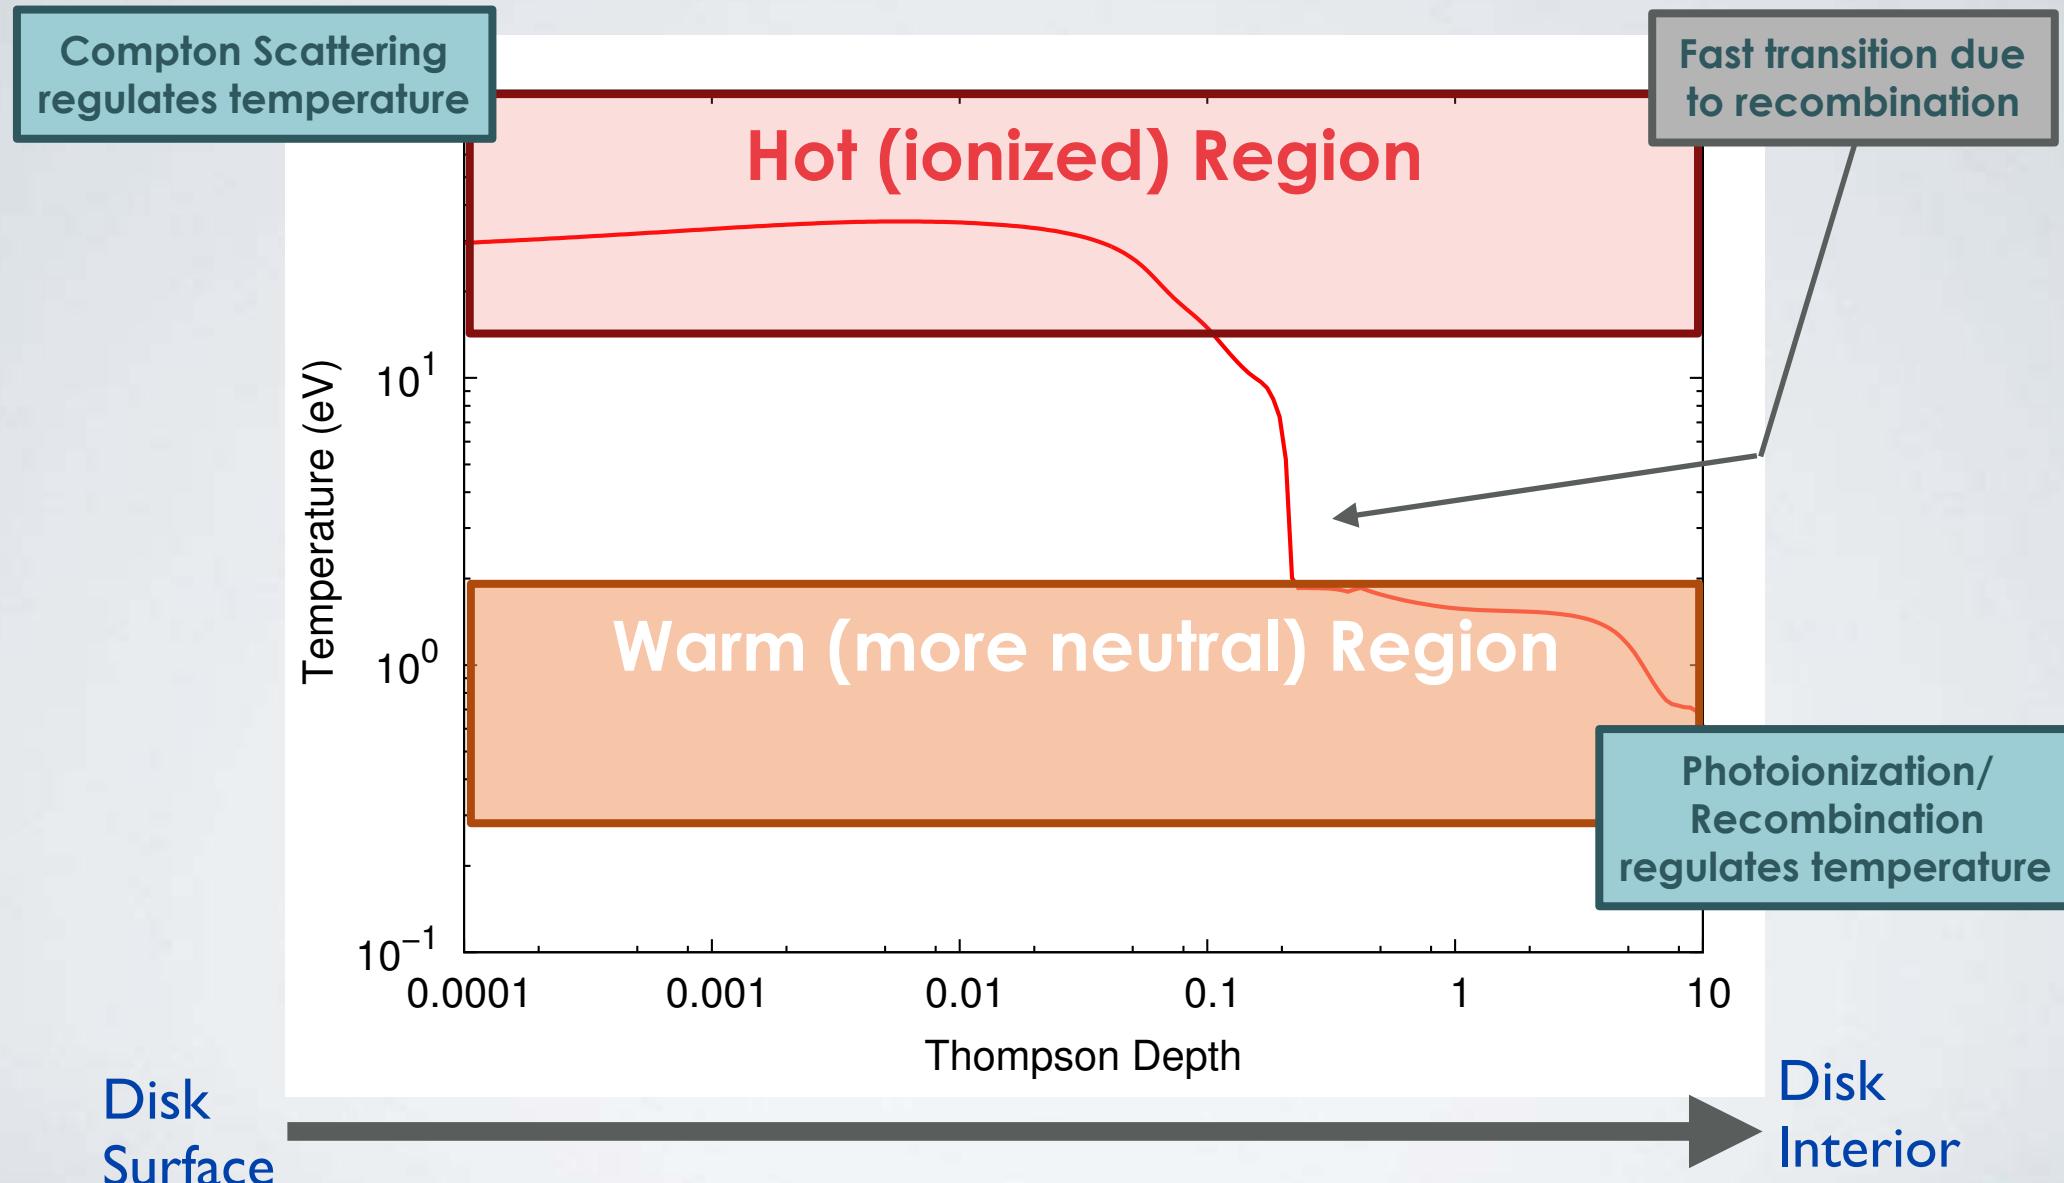

## Input Parameters

Ionization: Sets how strong is the illuminating field ( $\Xi$  =  $4\pi F_x/n_e$ ), where  $n_e=\text{const}$  is the gas density

Gamma: Sets the shape of the incident spectrum by assuming a  $E^\gamma$ -Gamma power-law

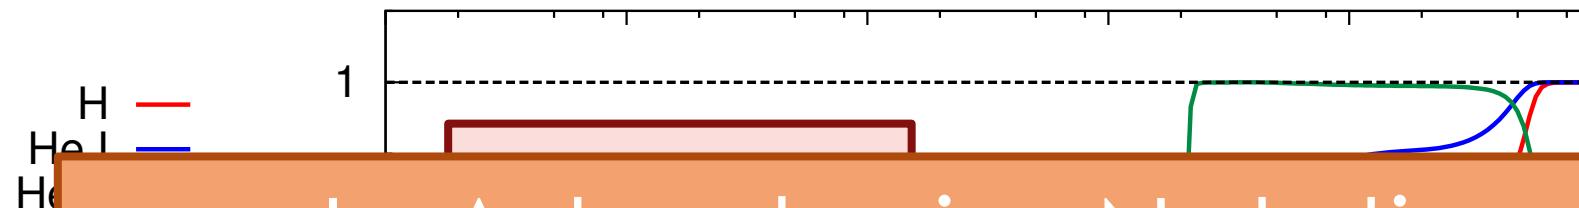

Afe: Sets the abundance of iron in Solar units

# XILLVER: Temperature Profiles

# XILLVER: Ionization Balance

The relative amount of each ion changes with the conditions of the gas

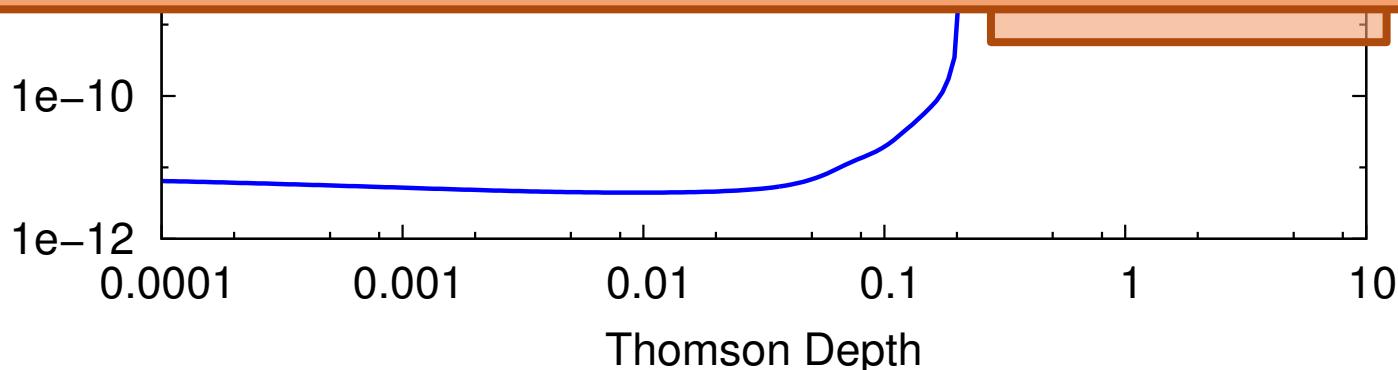

## In Astrophysics Notation:

He I = Neutral Helium

He II = Single Ionized (1 electron was removed)

He III = Doubly Ionized (2 electrons removed)

Etc.

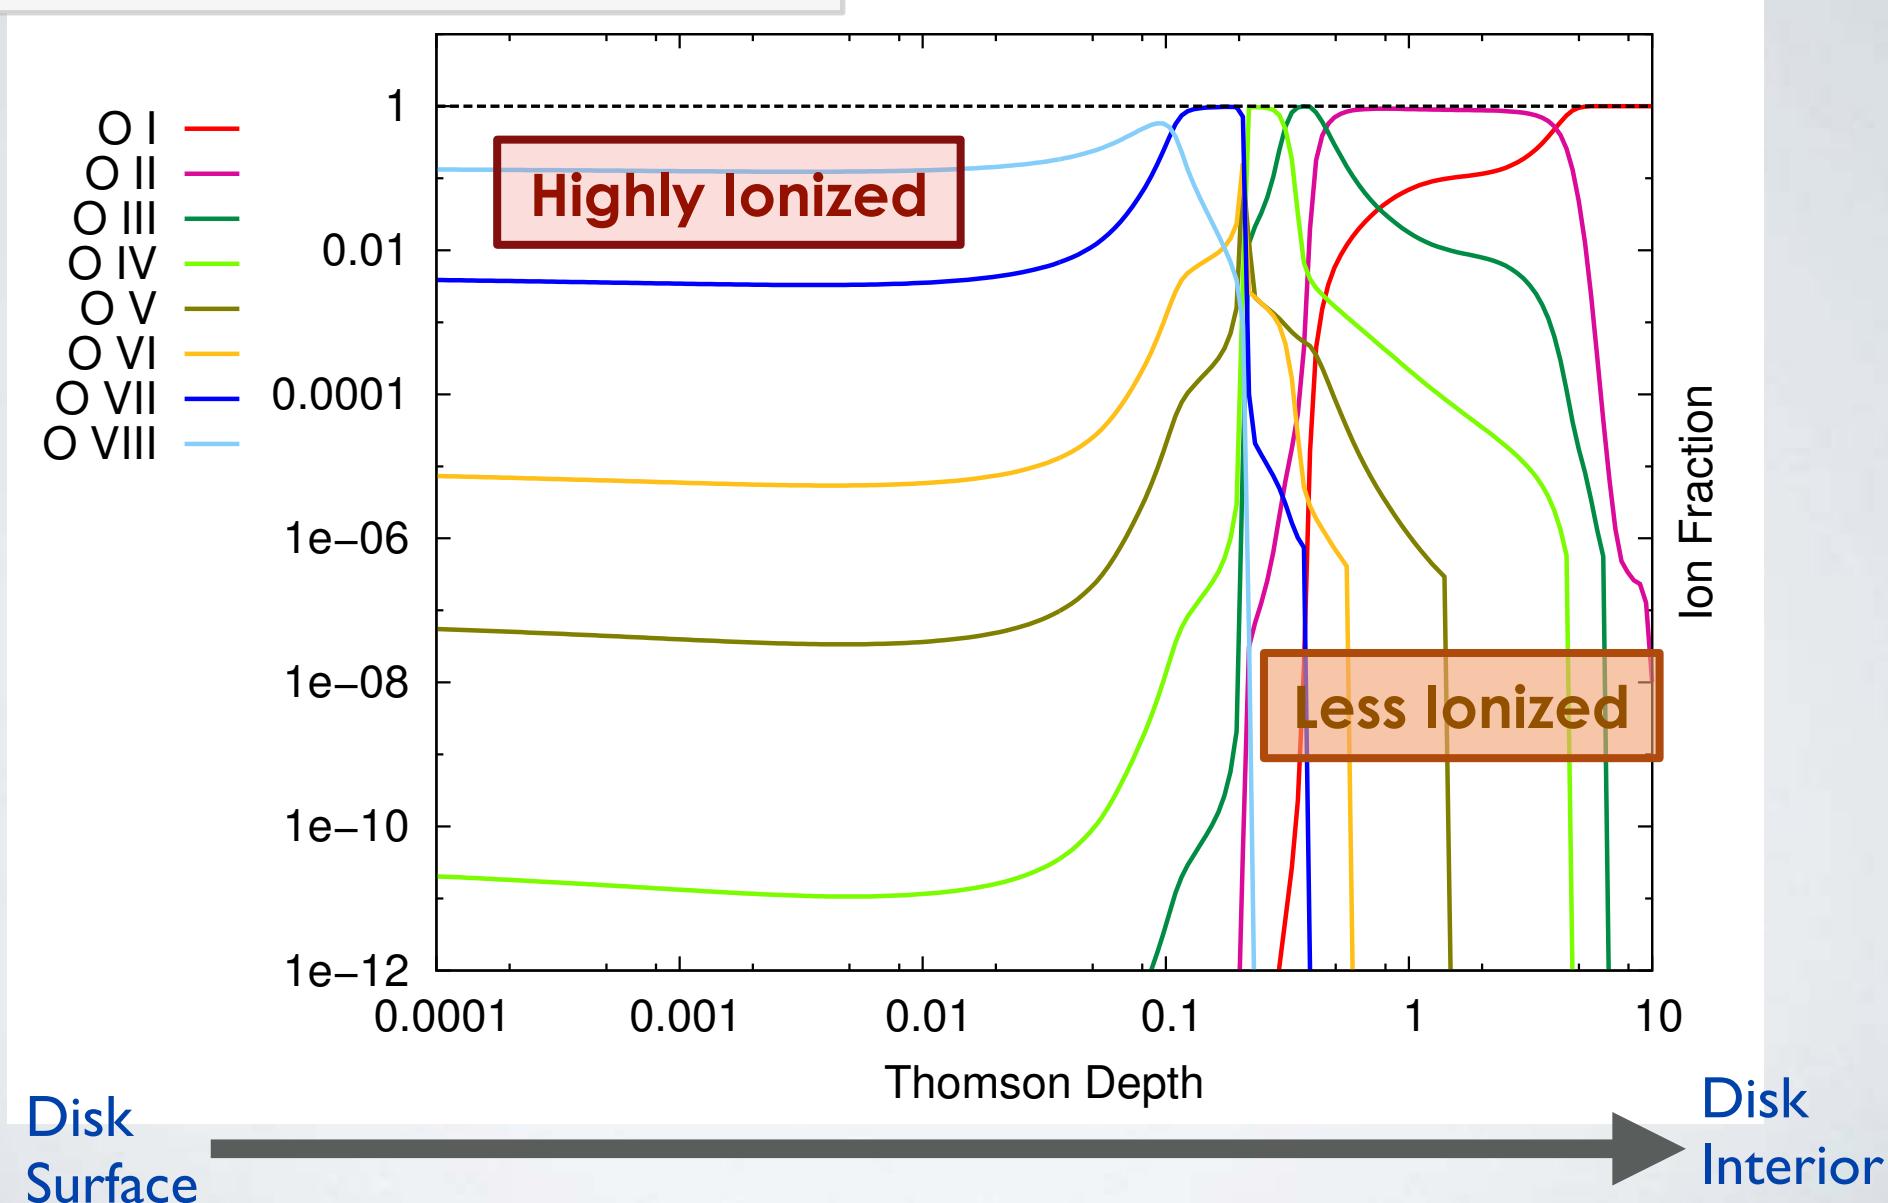

Disk  
Surface

Disk  
Interior

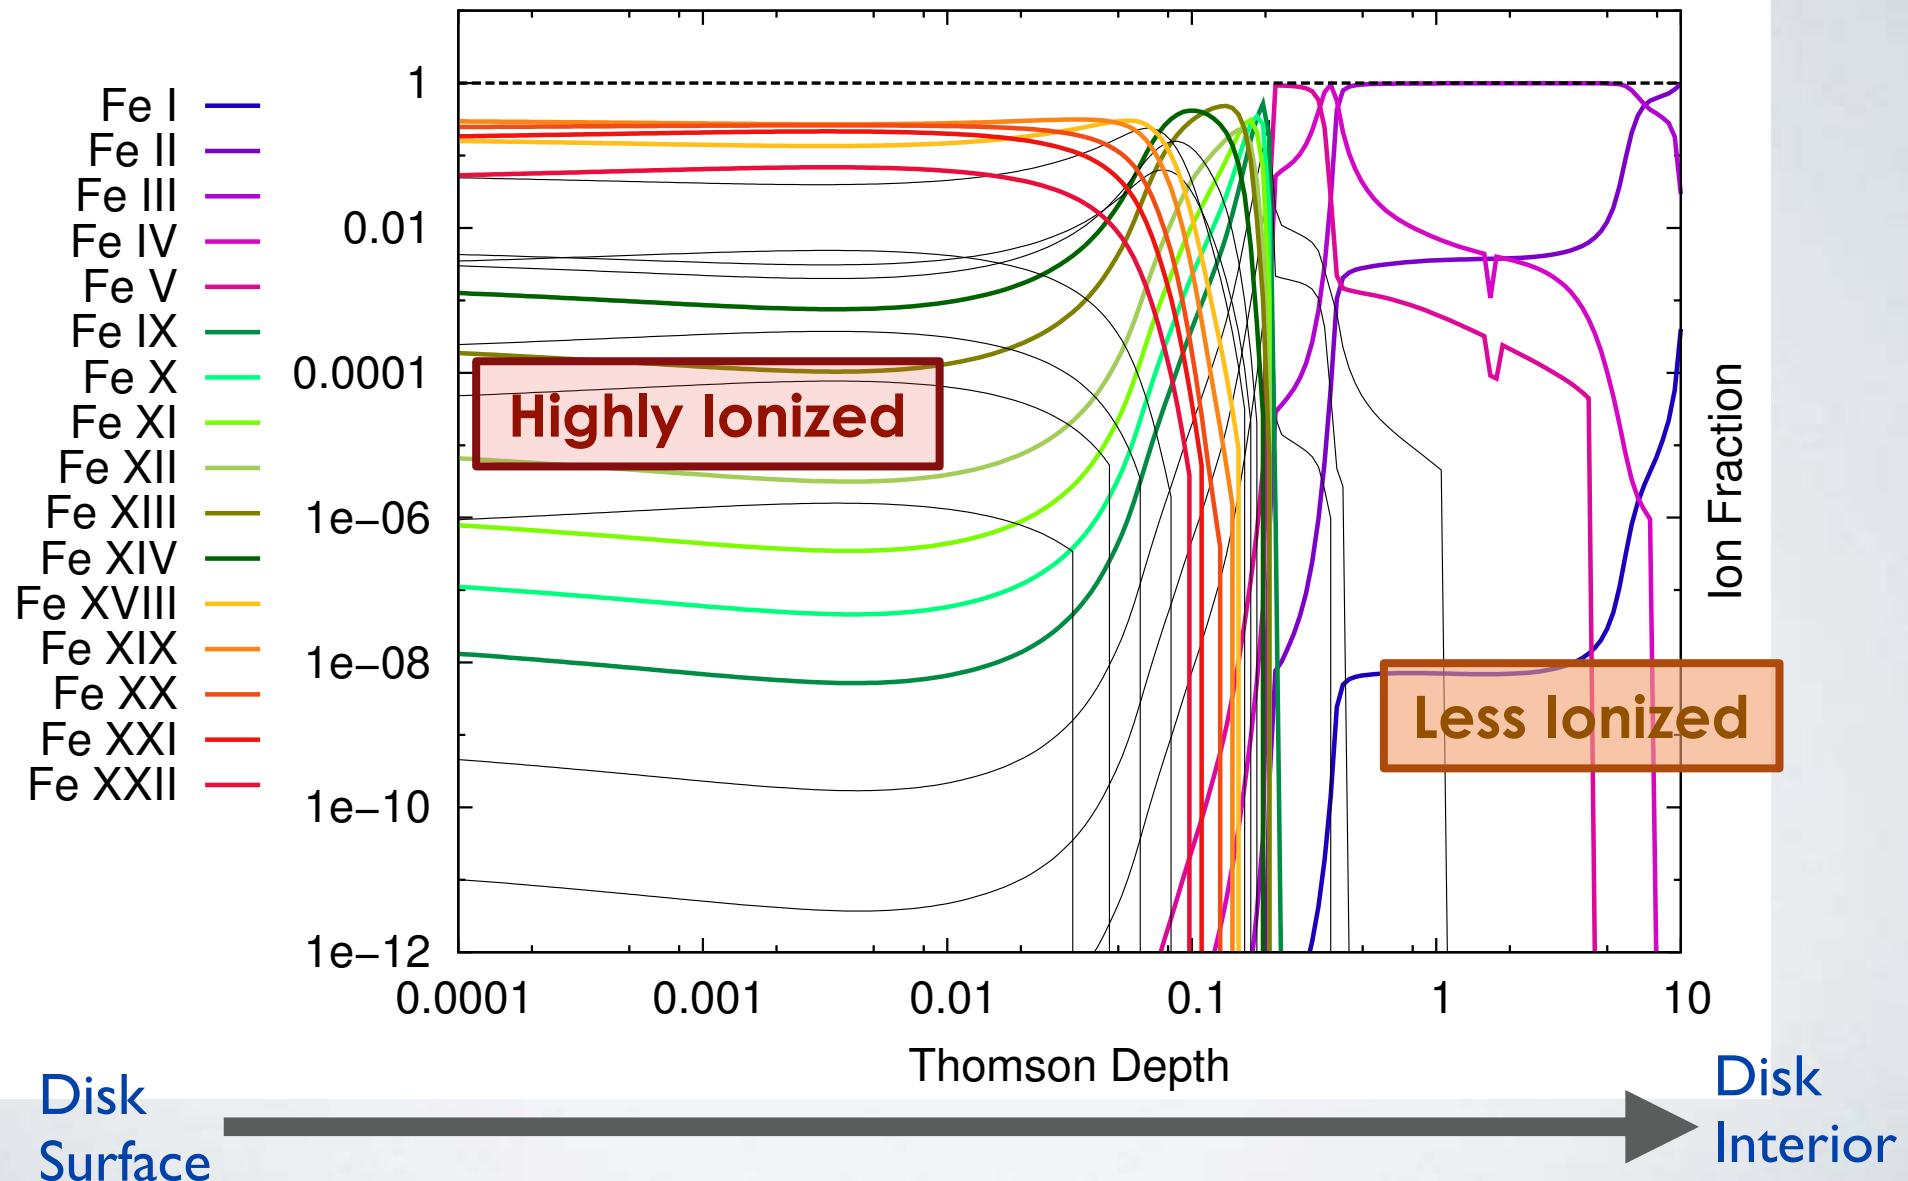

# XILLVER: Ionization Balance

The relative amount of each ion changes with the conditions of the gas

# XILLVER: Ionization Balance

The relative amount of each ion changes with the conditions of the gas

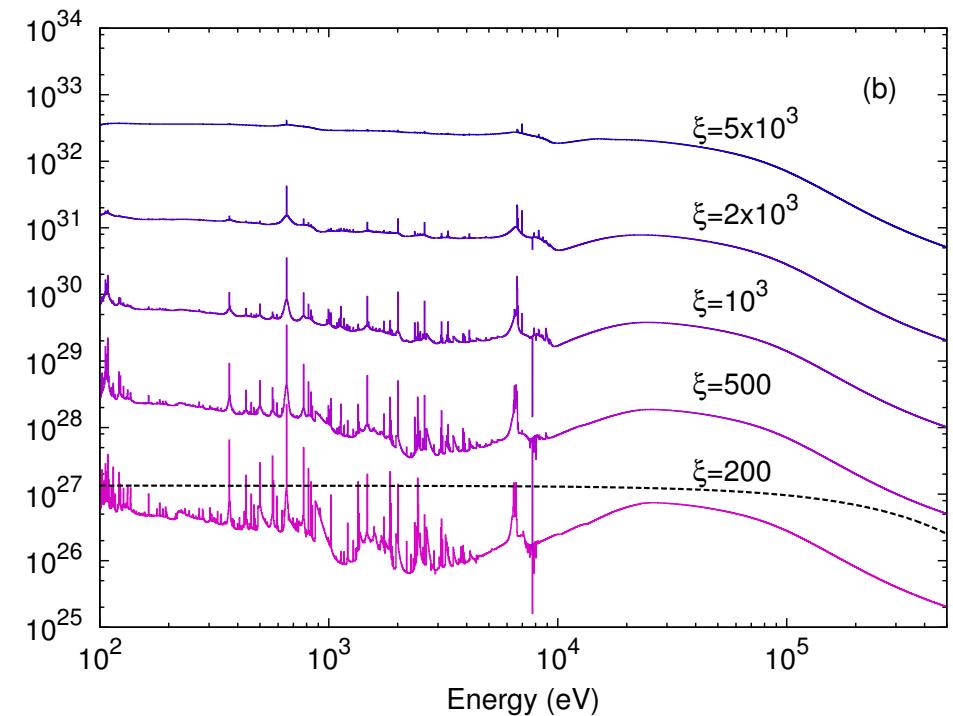

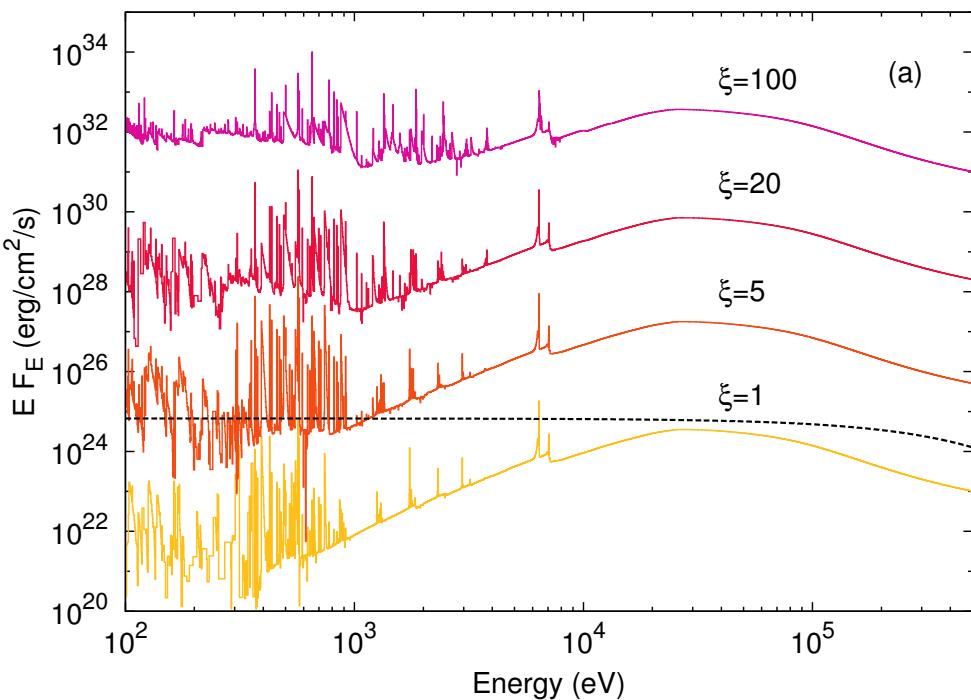

# XILLVER: Changing the ionization

The Ionization Parameter

$$\xi = \frac{4\pi F_x}{n_e}$$

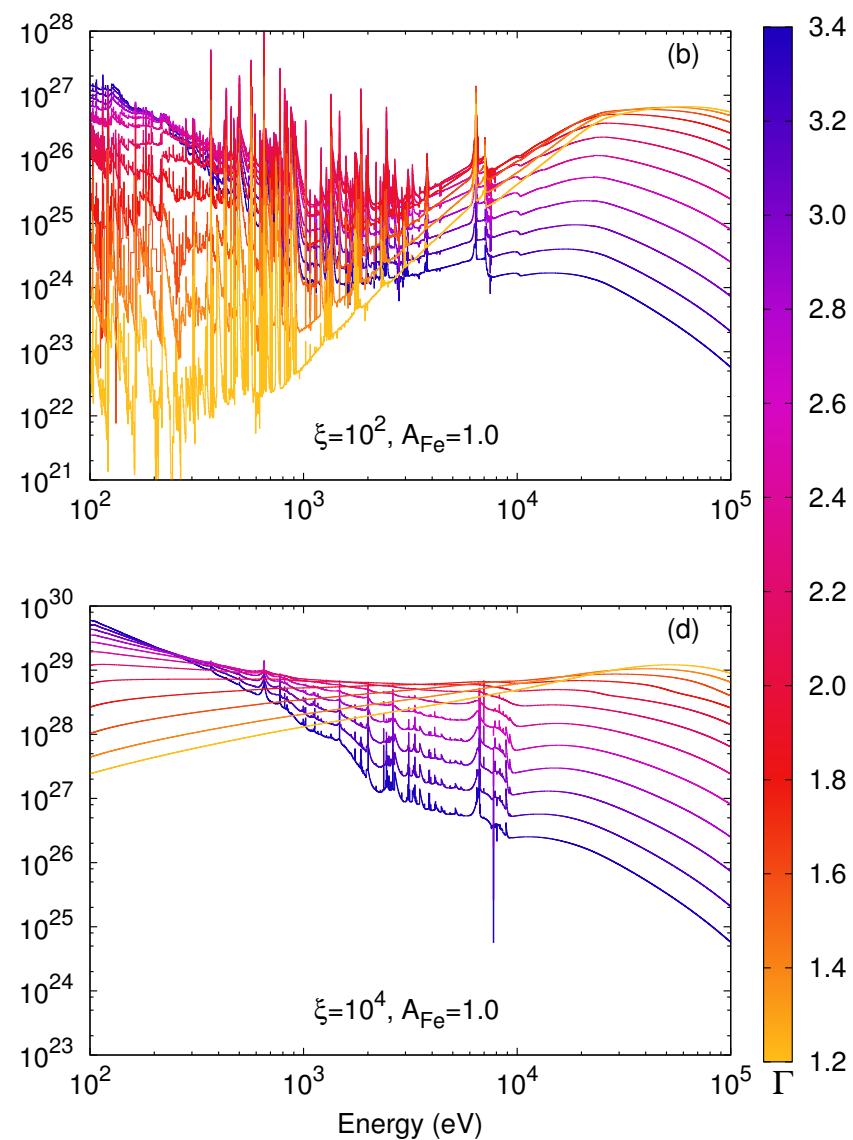

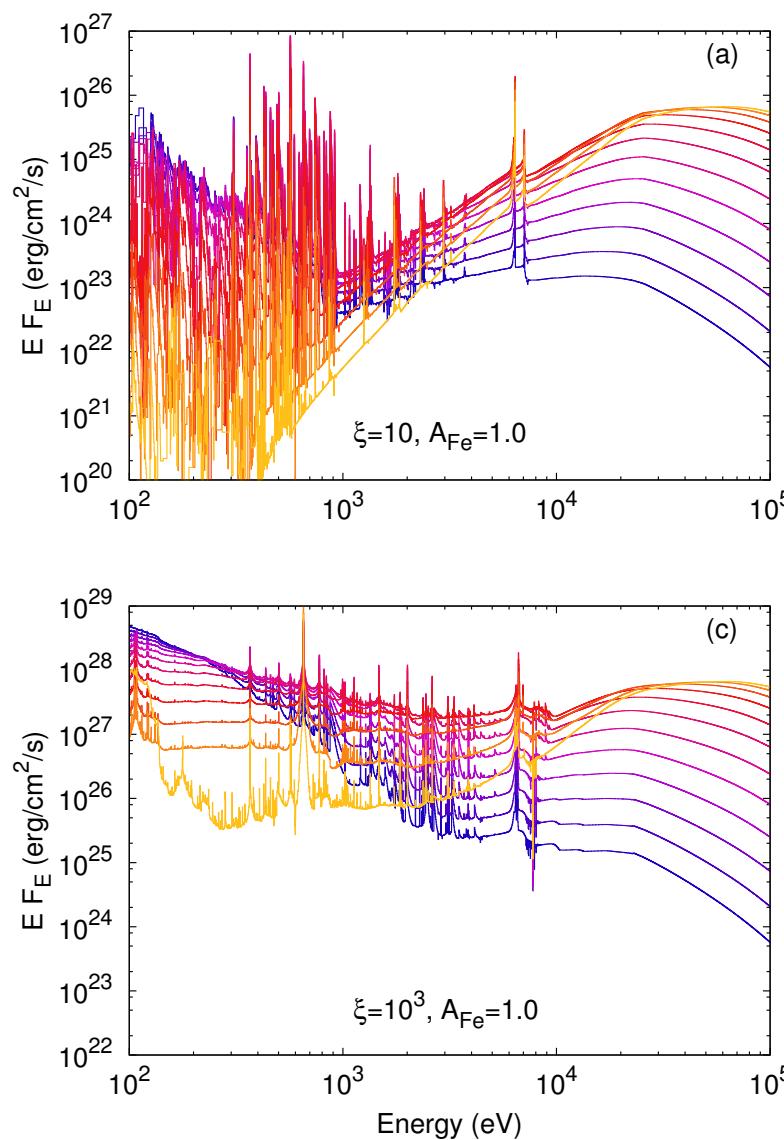

Integrated incident flux

Gas density (held fixed)

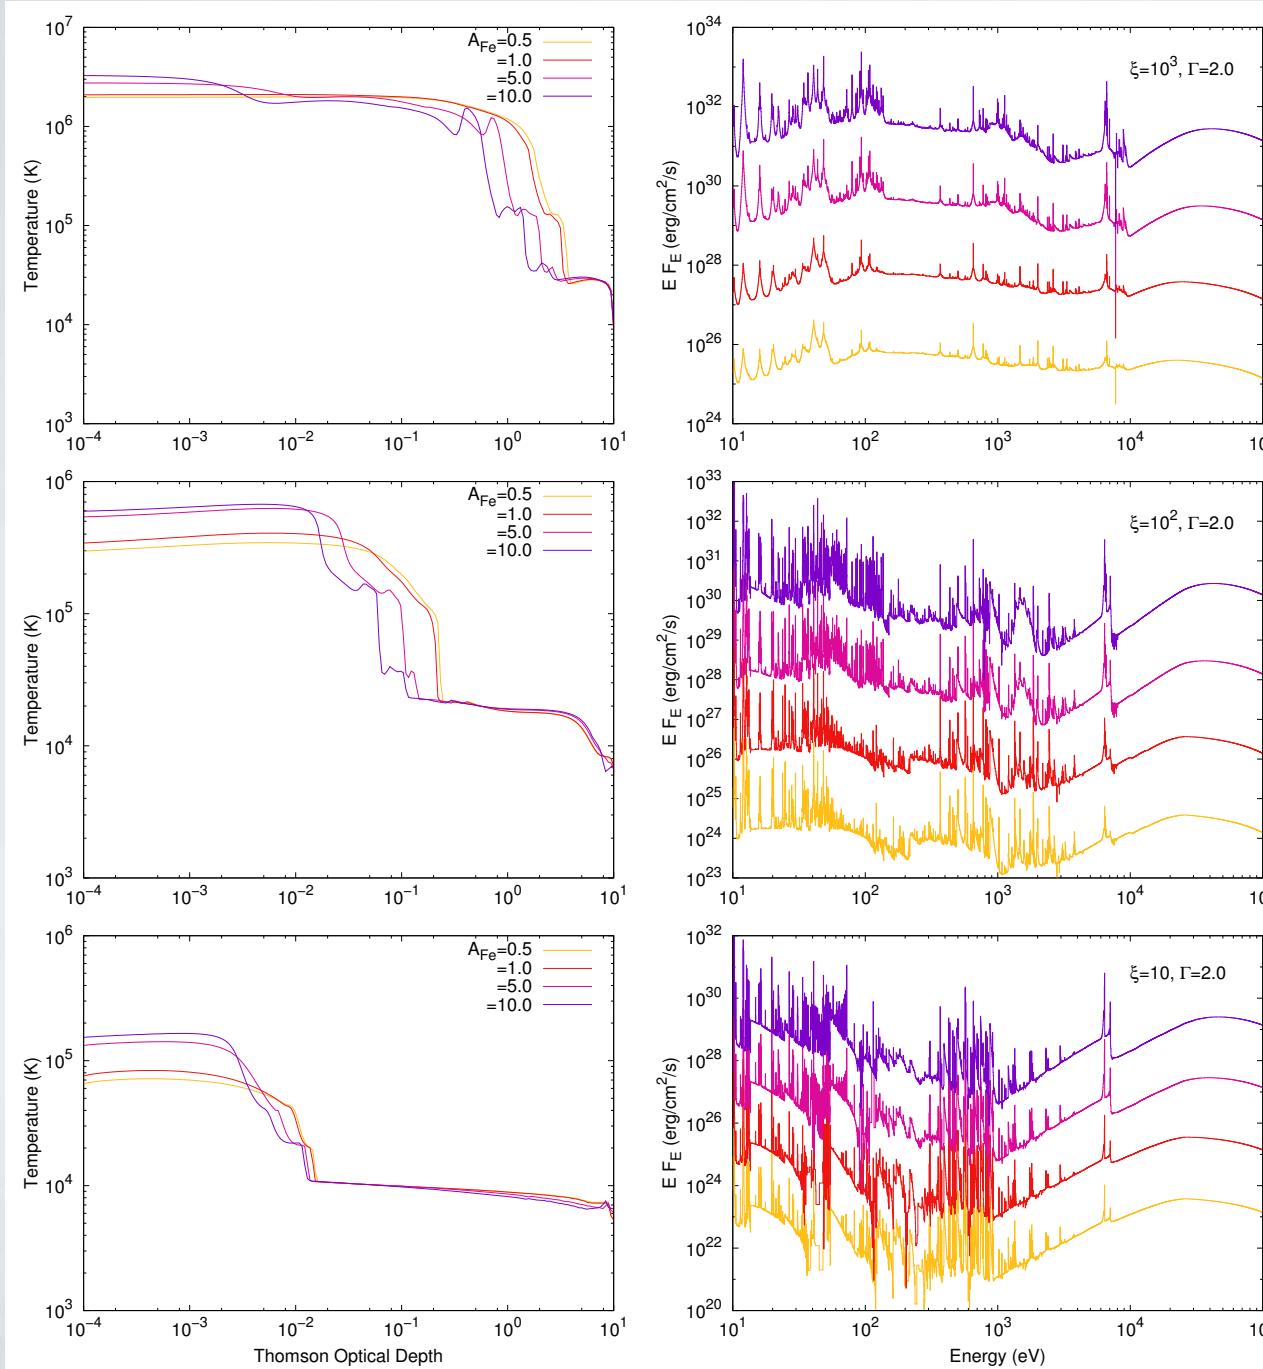

# XILLVER: Changing the Photon Index

The ionization parameter is the same, yet the changes are dramatic!

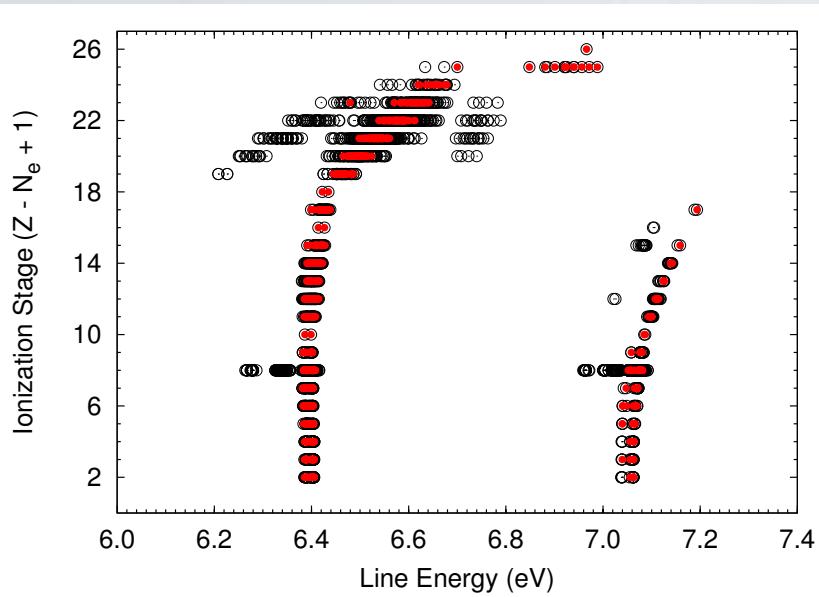

# XILLVER: Changing the Iron Abundance

The amount of iron (or any other metals) affects both the state of the gas and the spectrum.

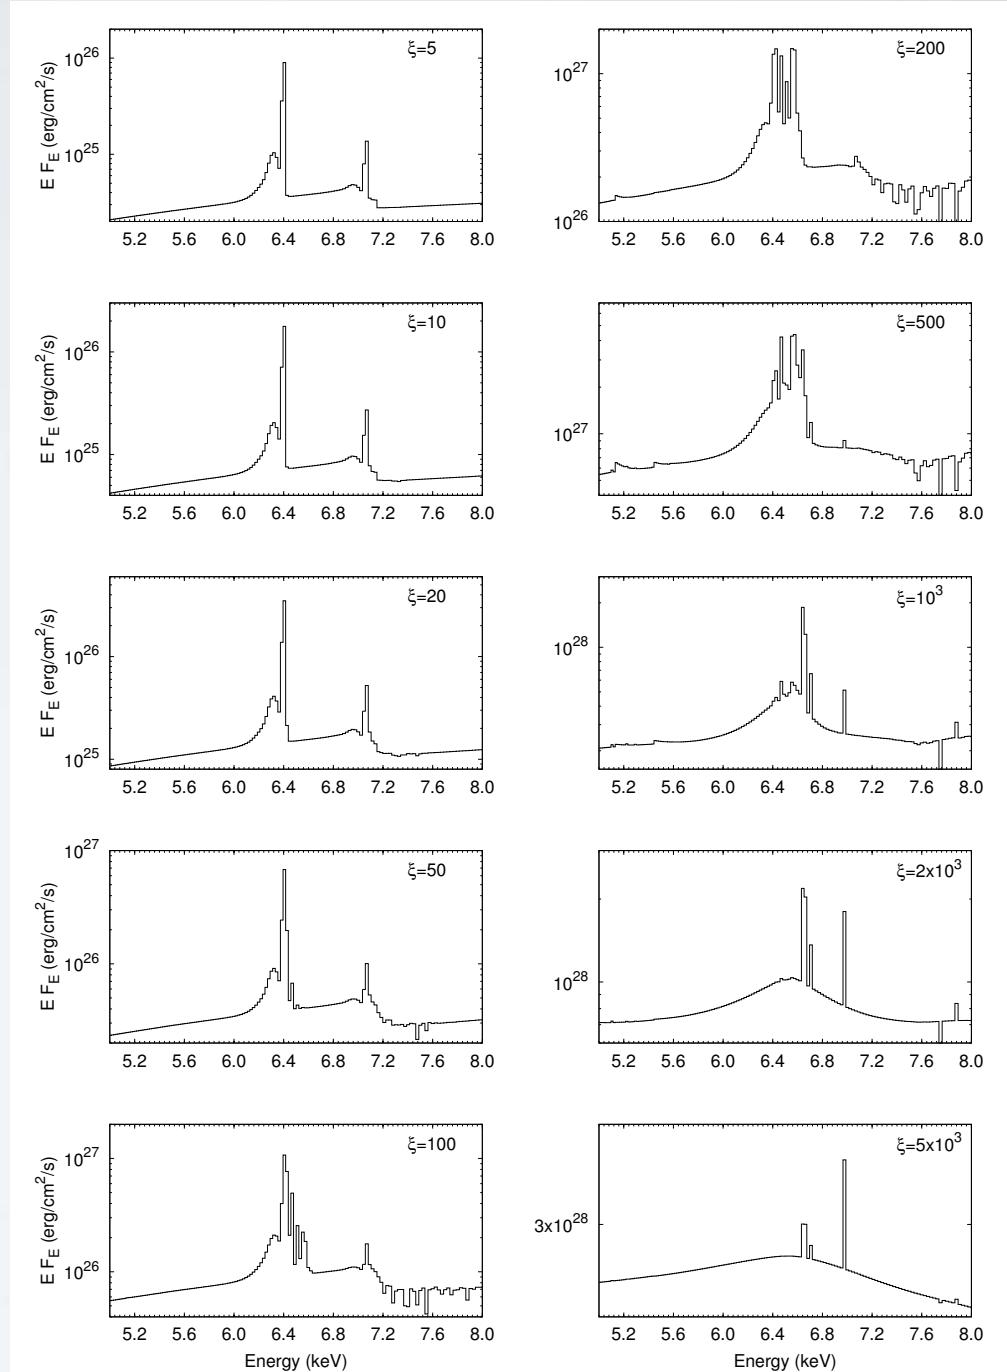

Higher Afe increases both the emission and absorption!

# XILLVER: The Fe K Emission Complex

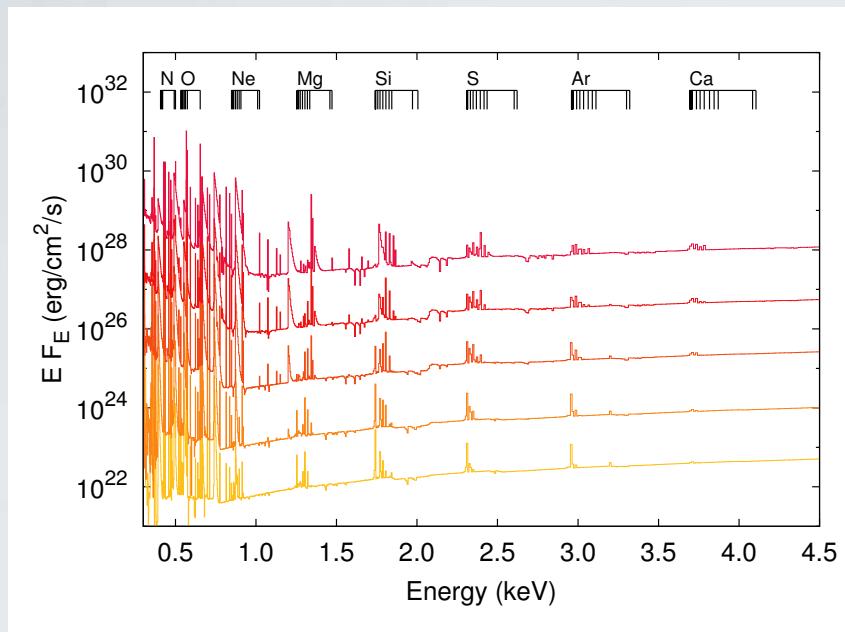

The emission of Fe in the 6-8 keV range is due to a large number of transitions

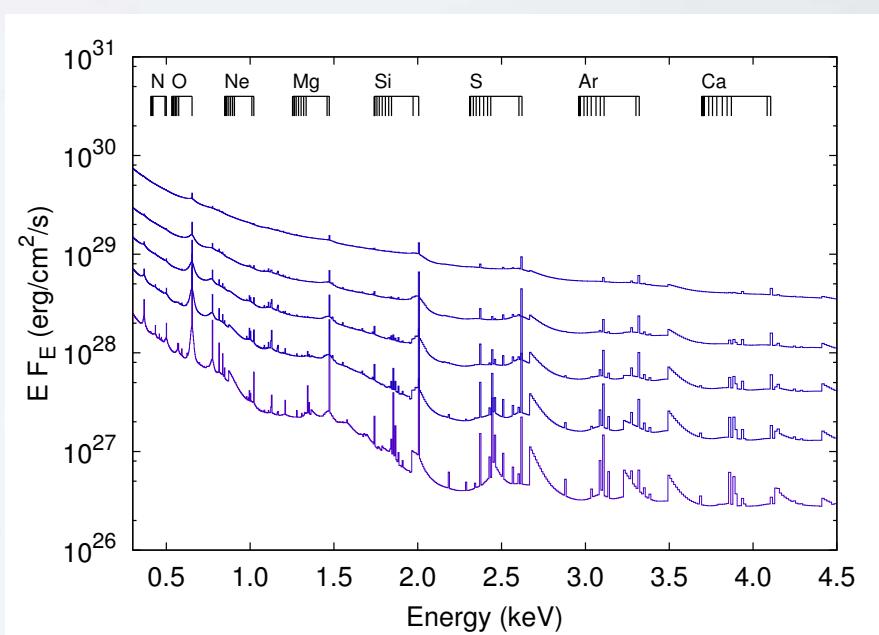

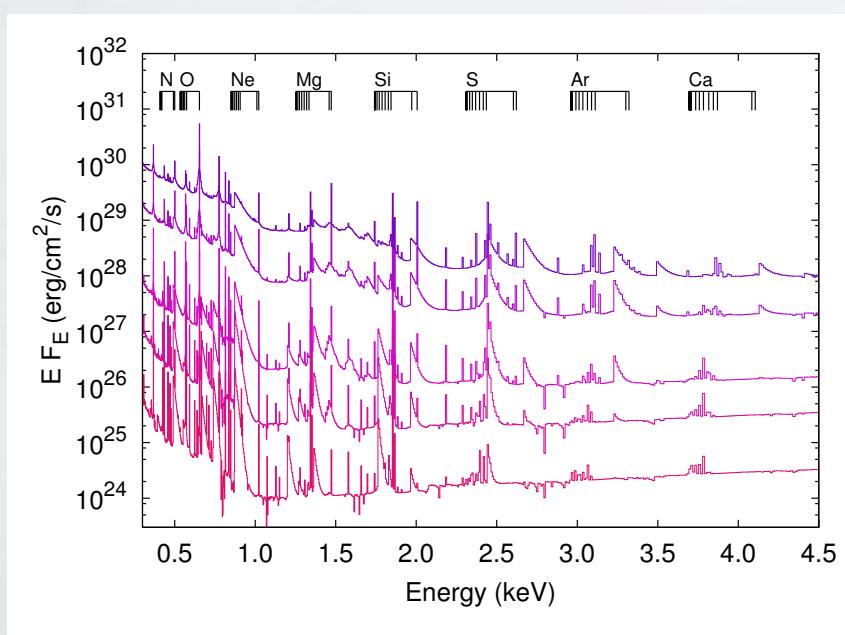

The line energy changes according with the ionization stage

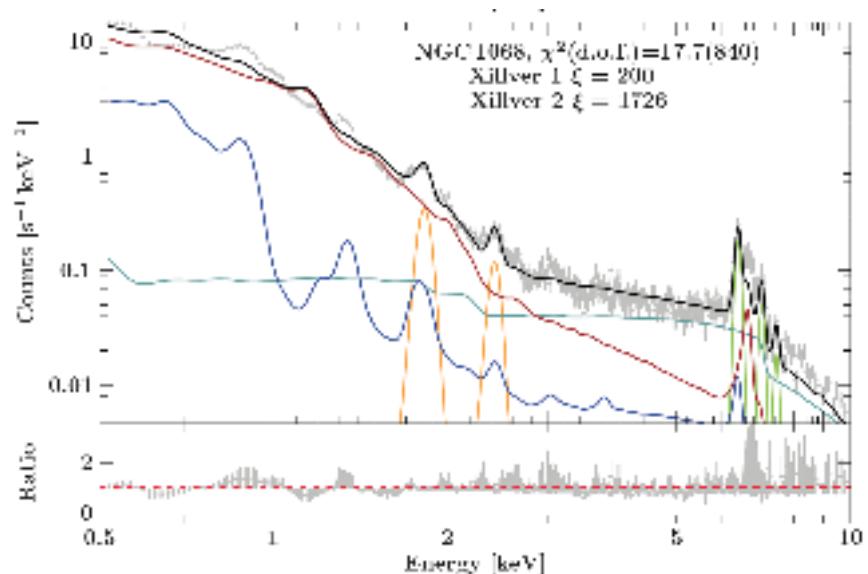

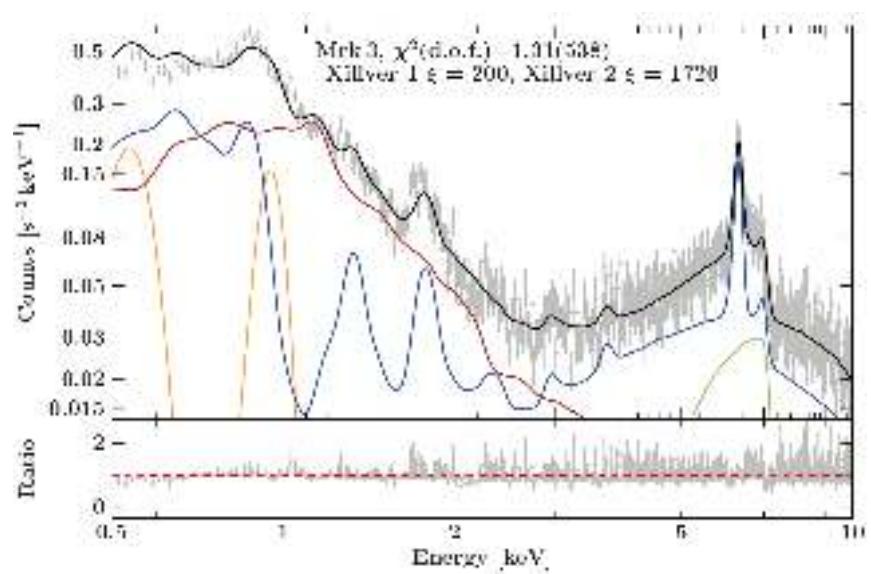

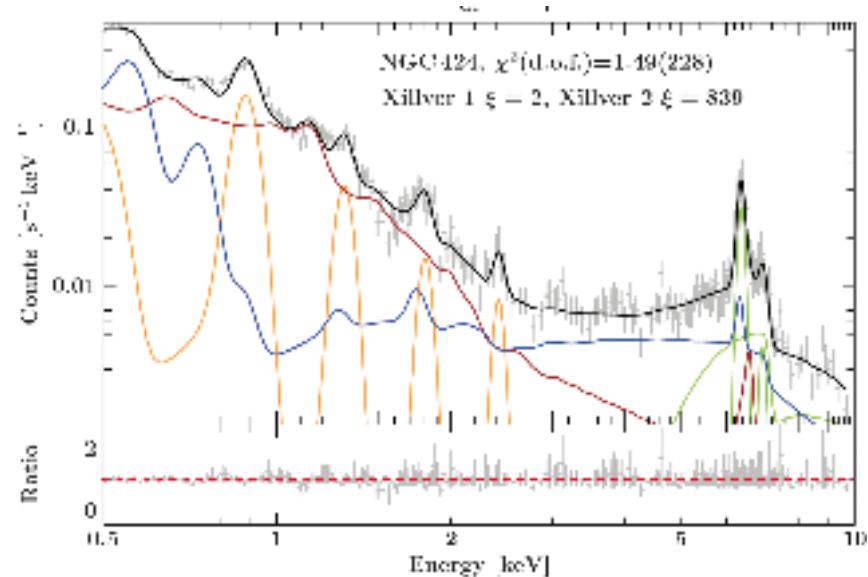

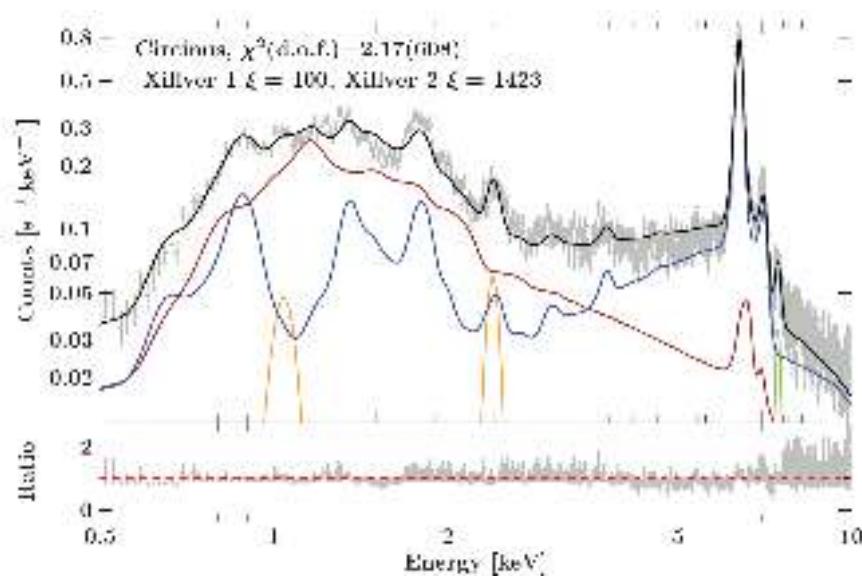

# XILLVER: More than Iron

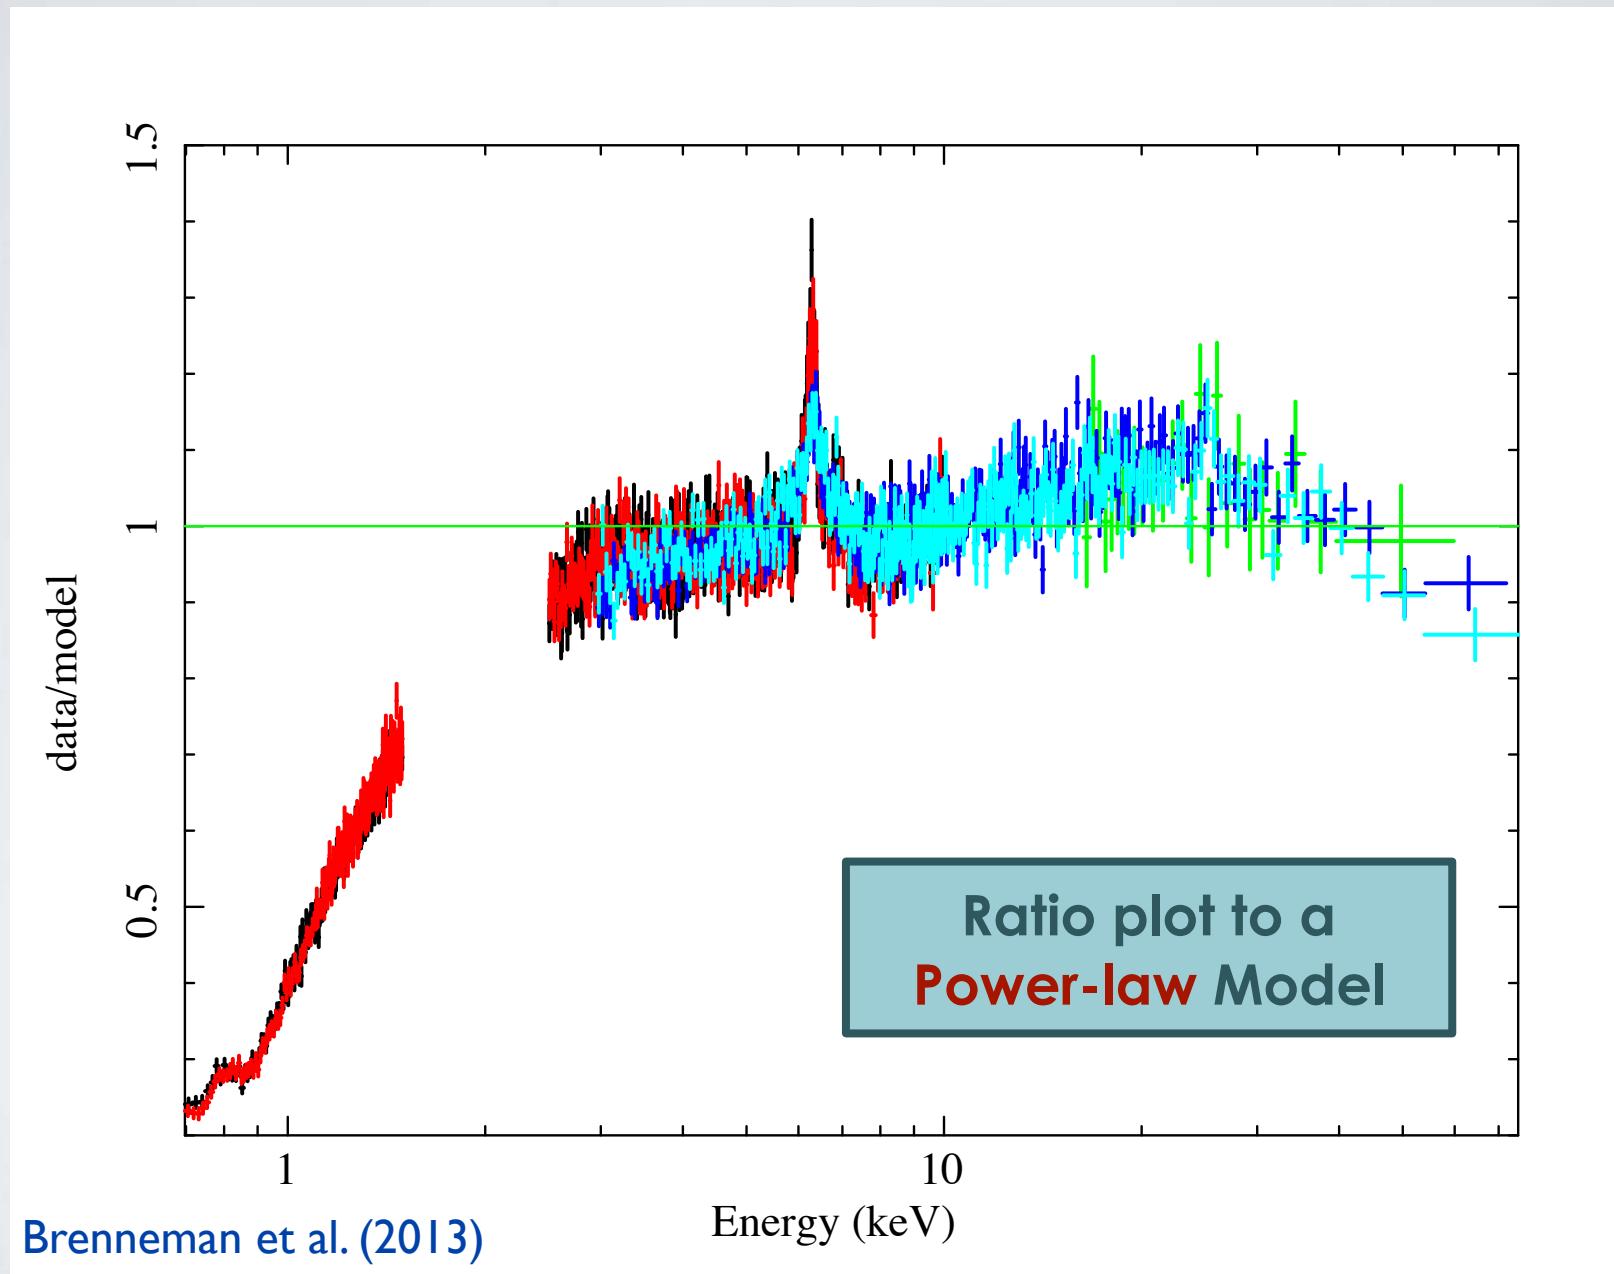

XILLVER includes all  
astrophysically relevant ions

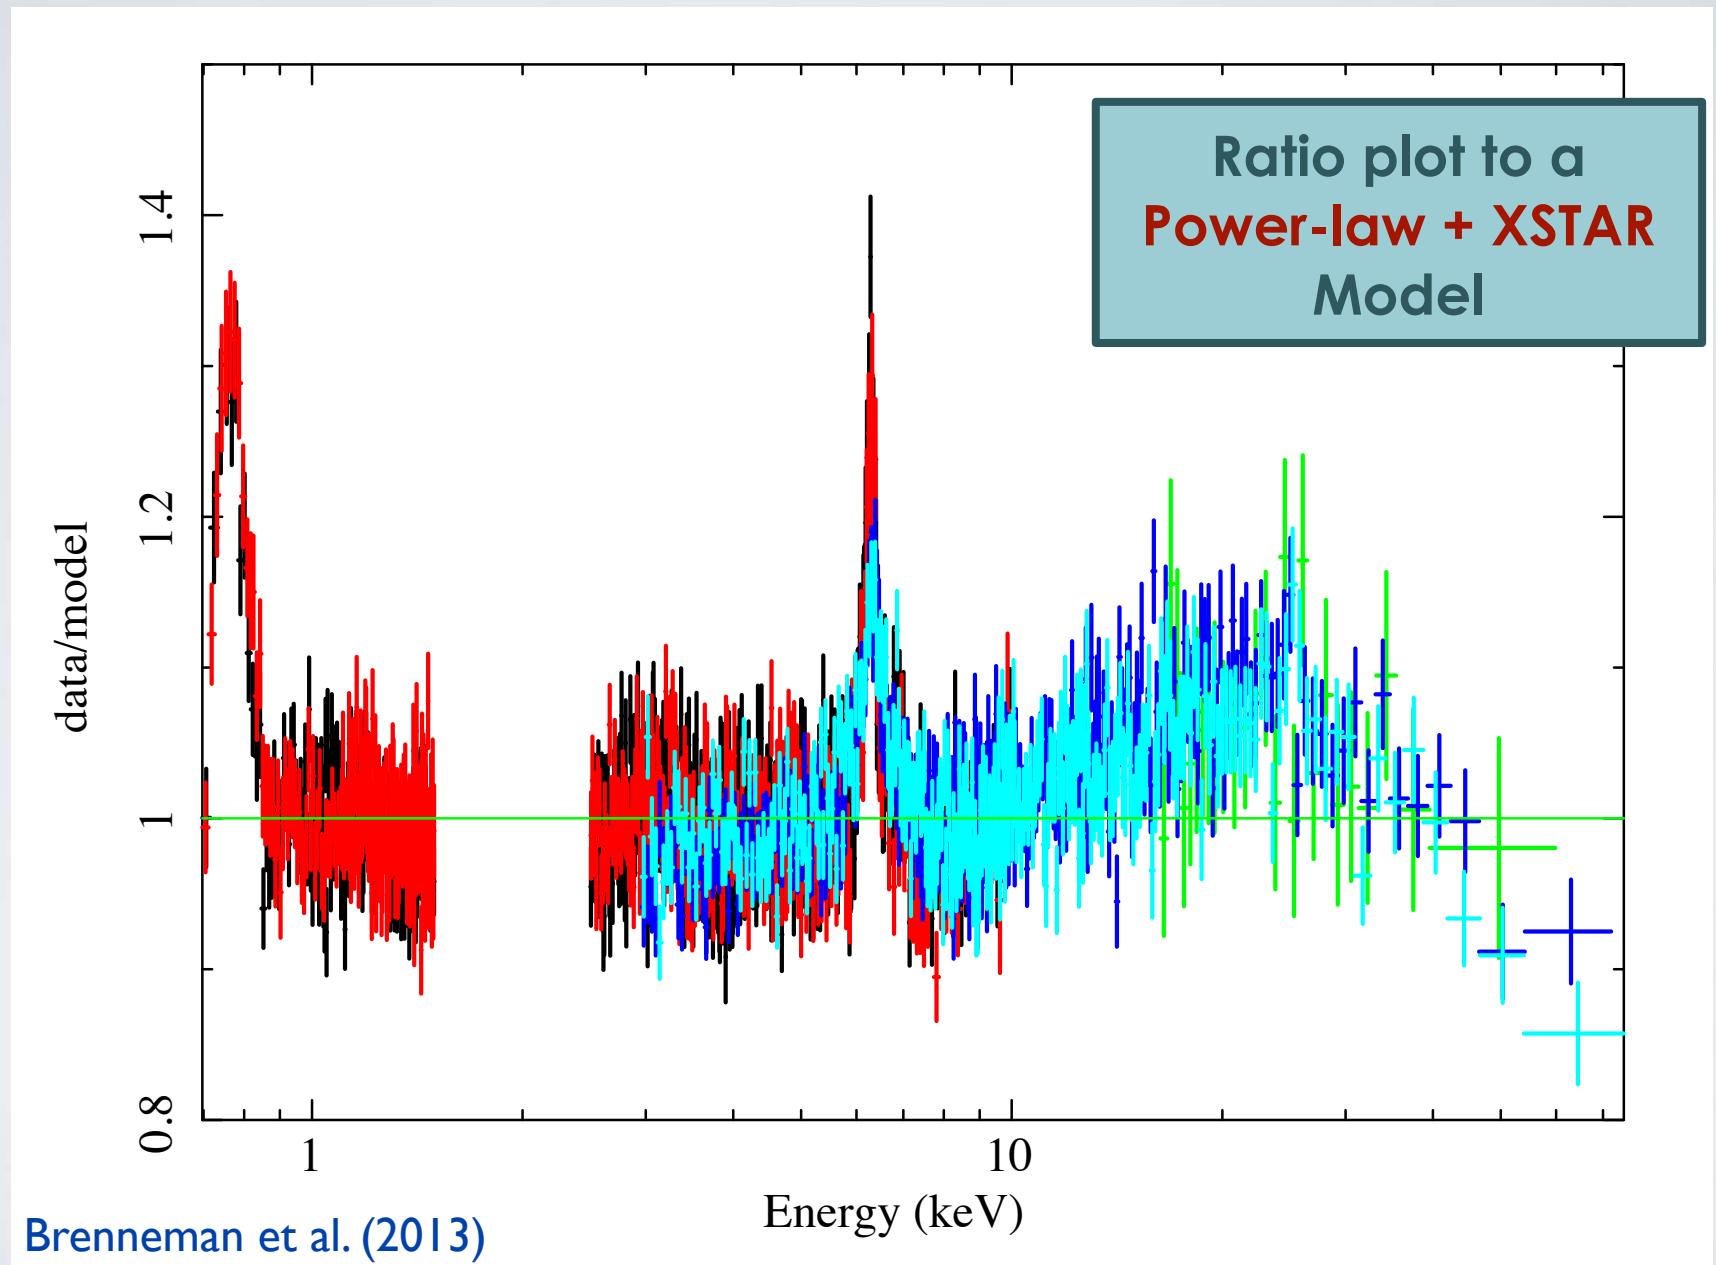

# XILLVER: More than Iron

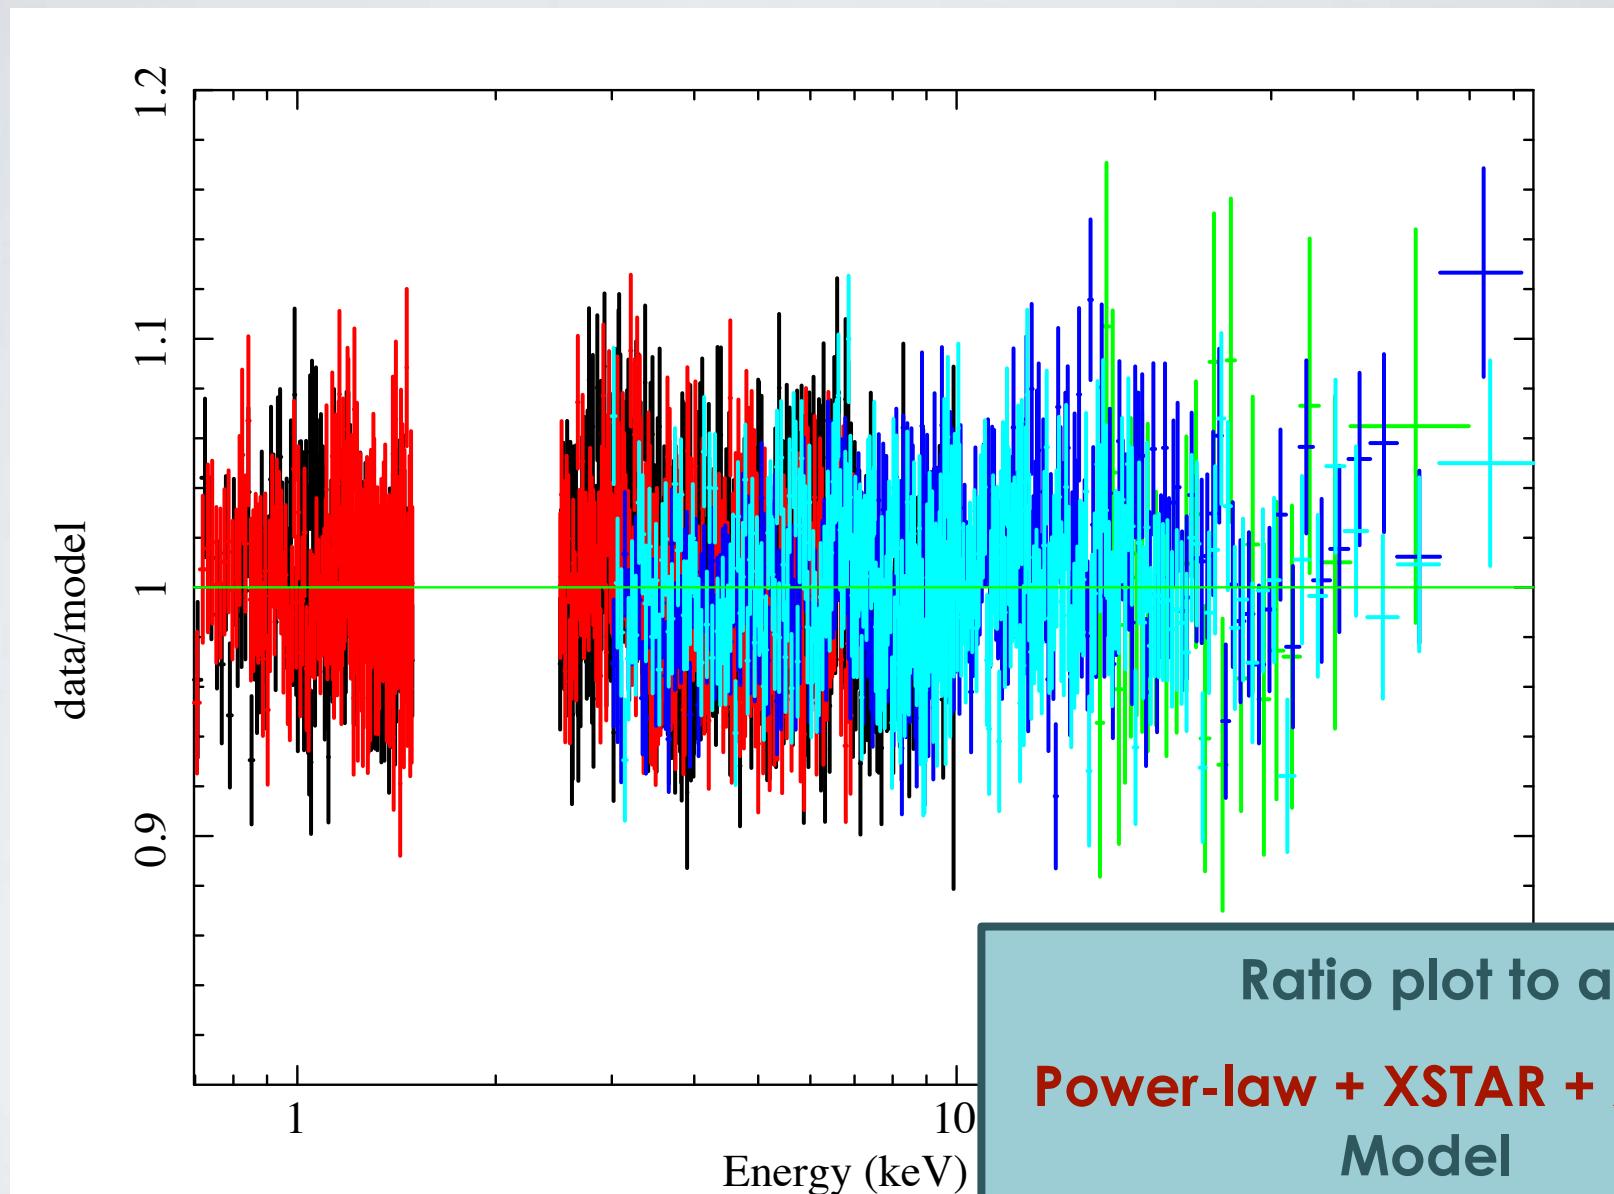

# XILLVER: Cold Reflection in IC 4329A

# XILLVER: Cold Reflection in IC 4329A

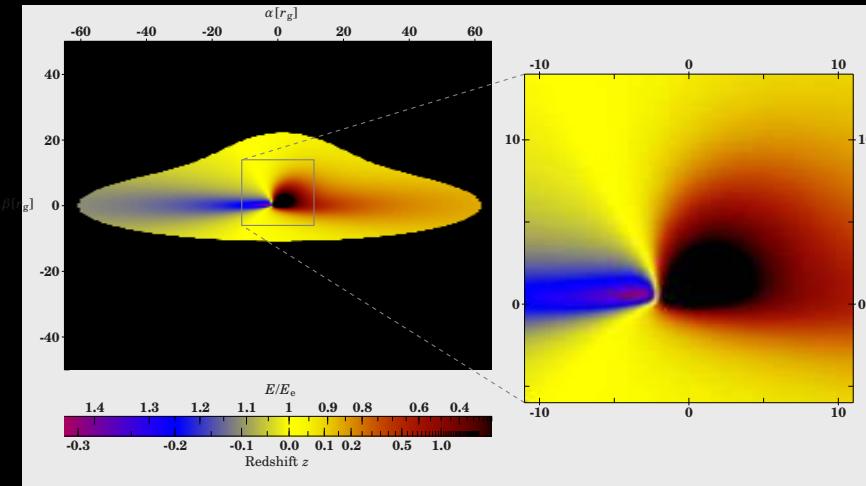

# XILLVER: Cold Reflection in IC 4329A

**Relativistic effects also need to  
be accounted for!**

# Modeling Relativistic Reflection

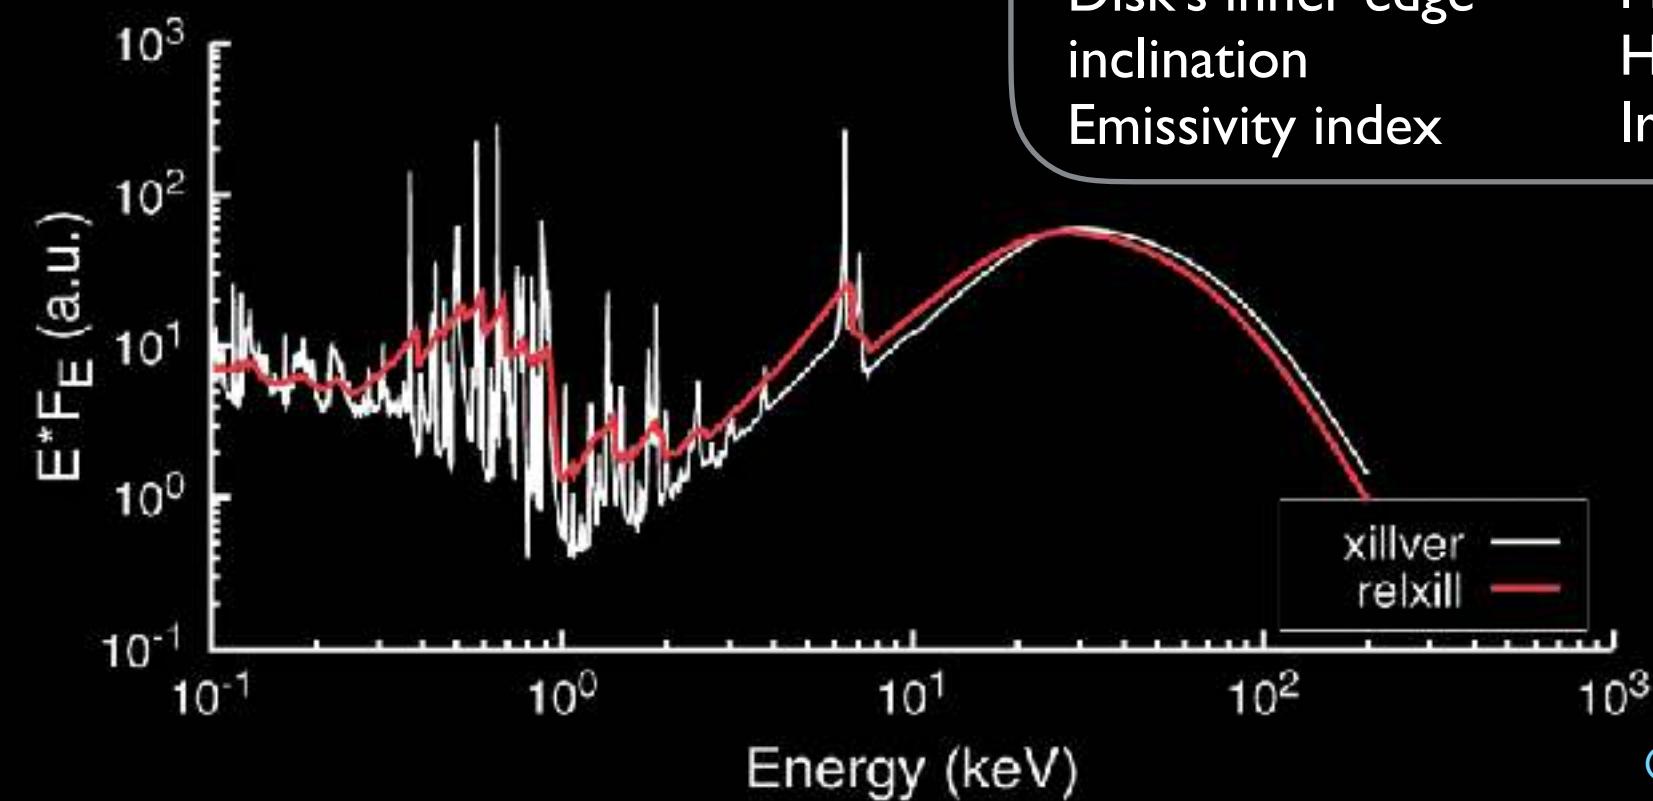

The **relxill** model: Combines ionized reflection spectra from **xillver** (Garcia & Kallman 2010), with the relativistic blurring code **relline** (Dauser et al. 2010)

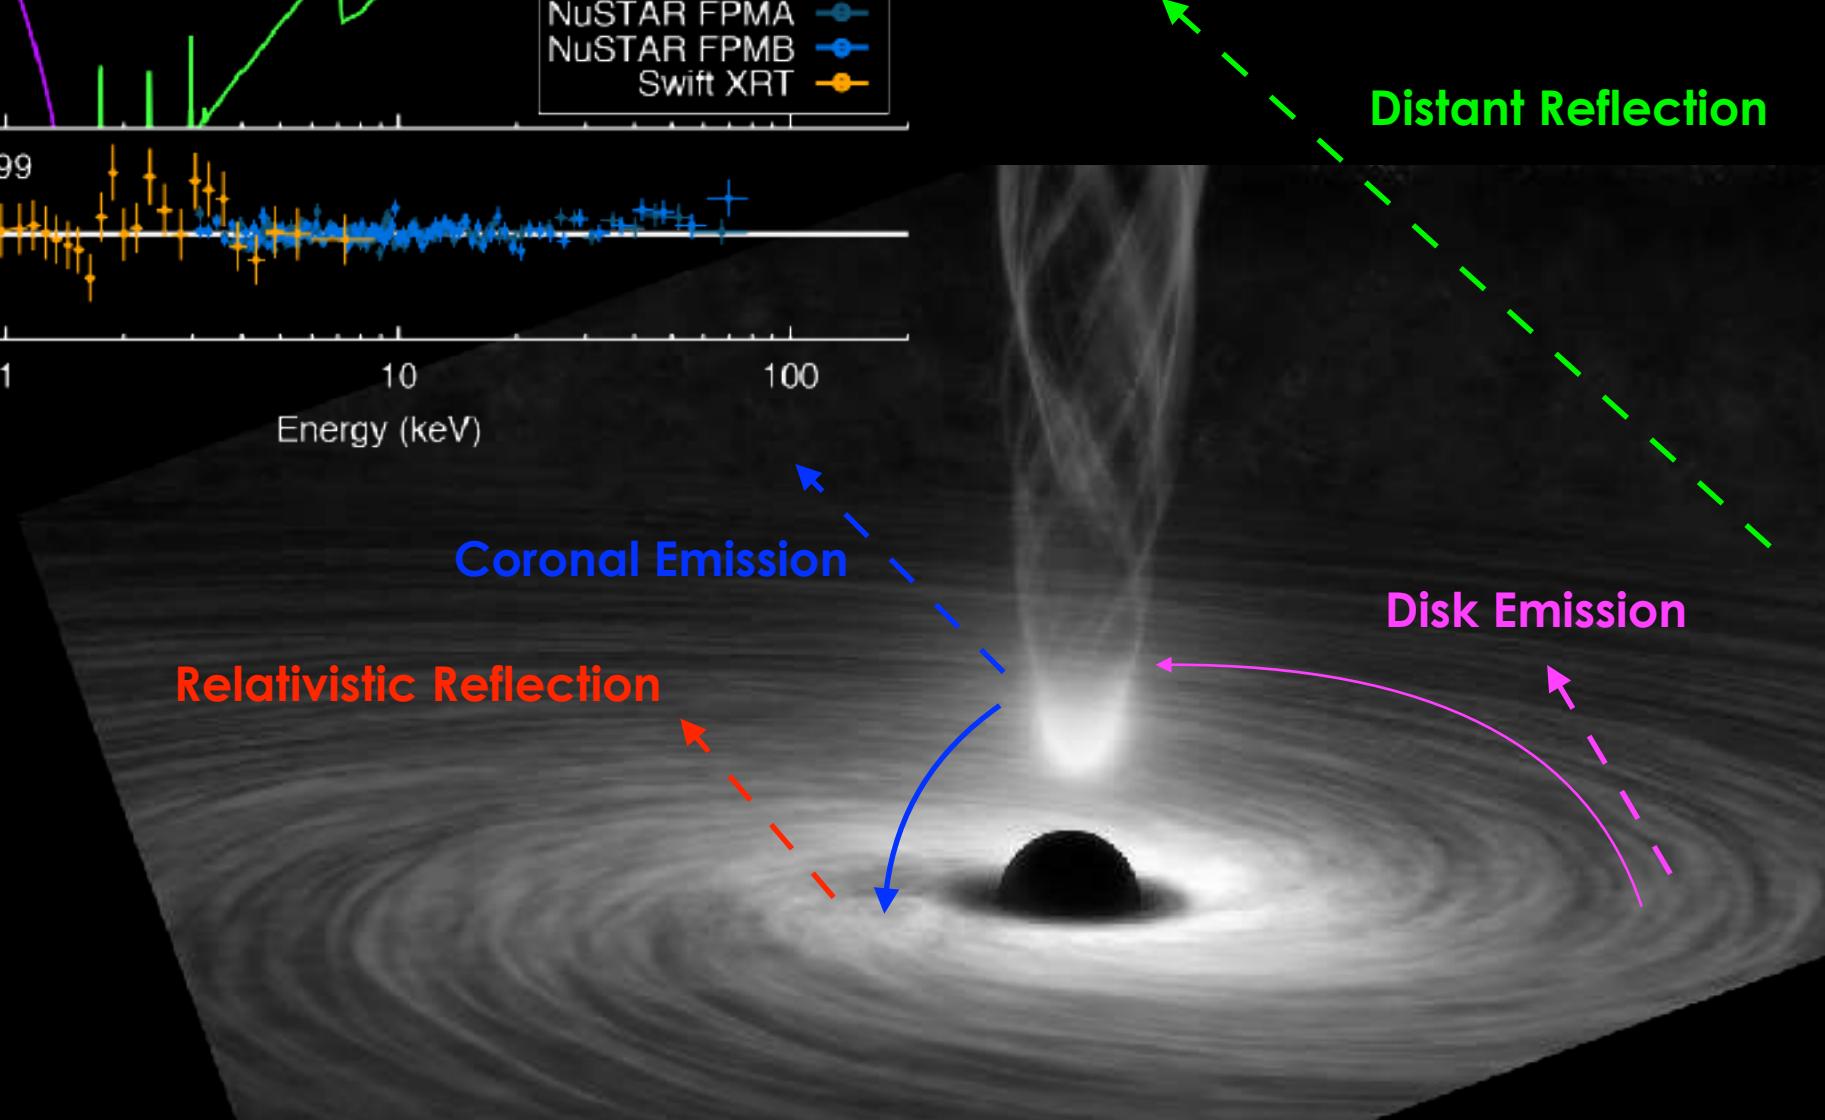

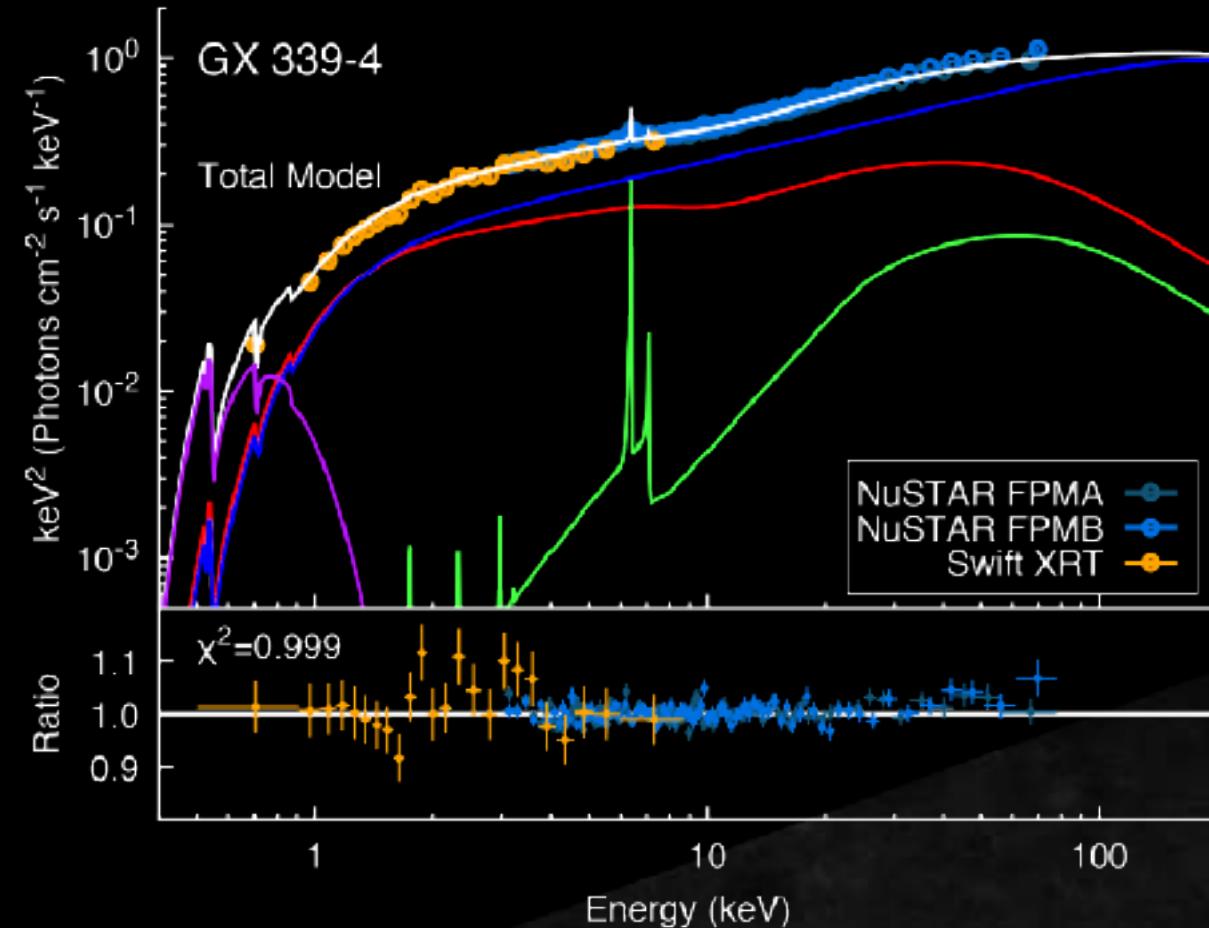

## Model parameters:

Black hole spin  
Disk's inner edge  
inclination  
Emissivity index

Reflection fraction  
Photon index  
High energy cutoff  
Iron abundance

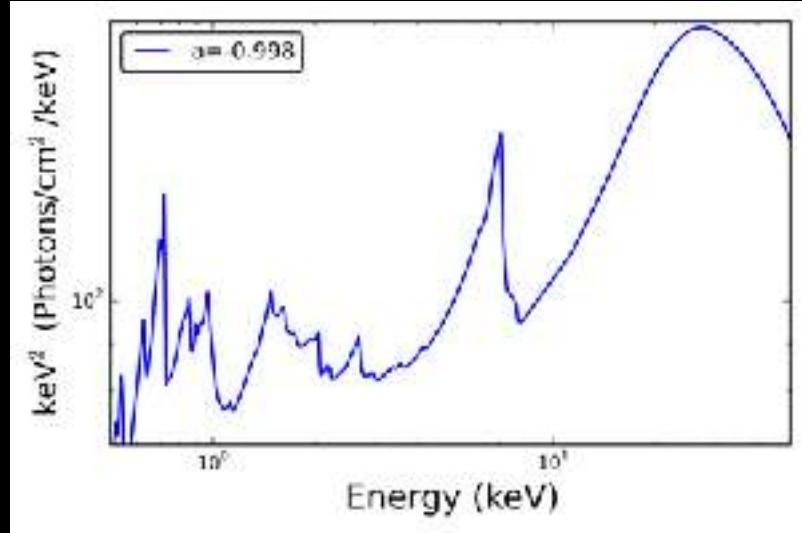

García et al. (2014)

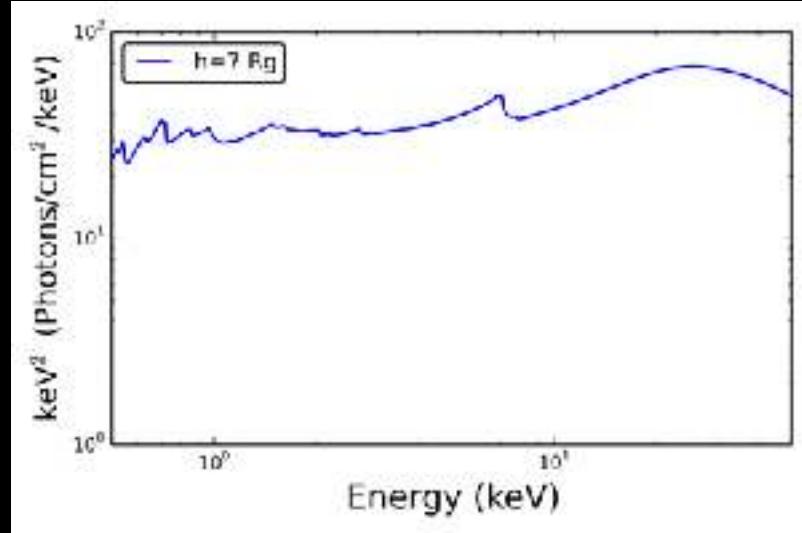

# Constraining Physical Quantities

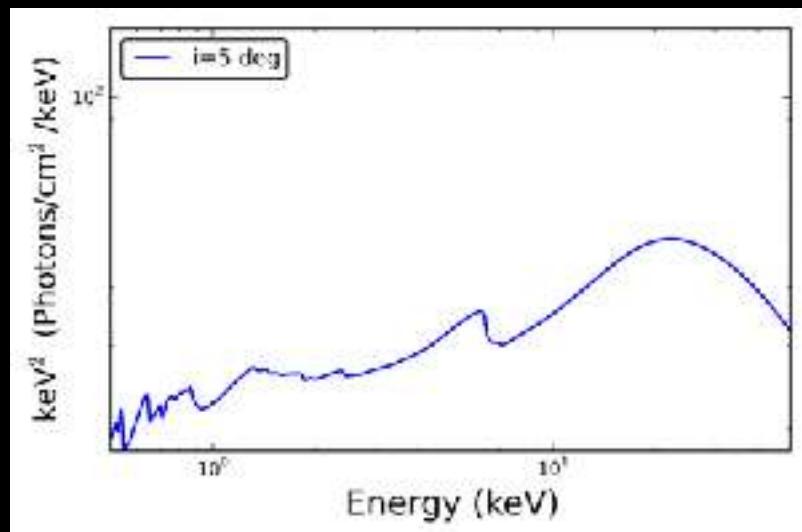

Black Hole Spin

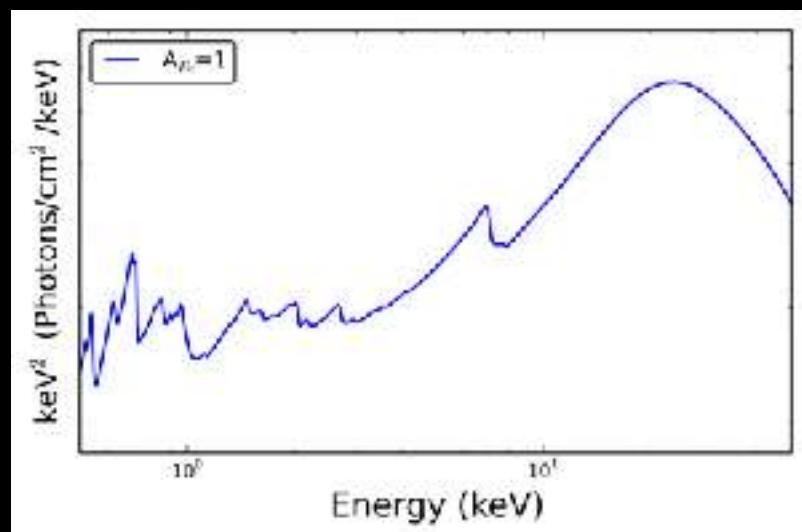

Coronal Height

Inclination

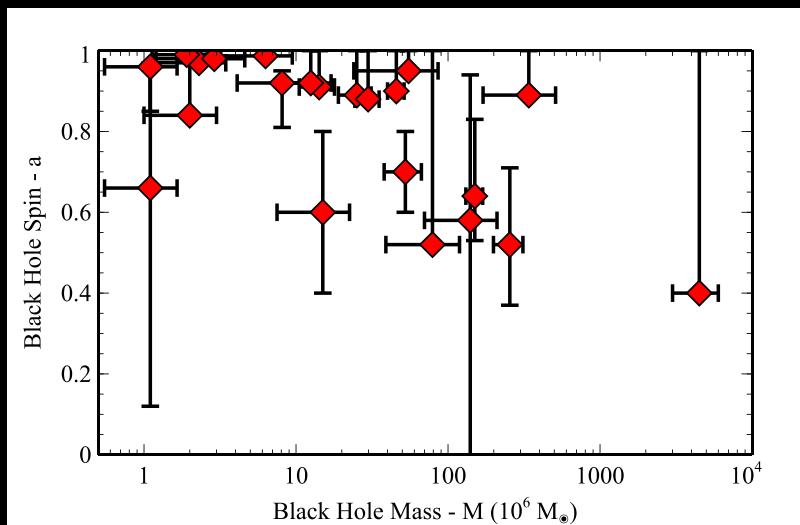

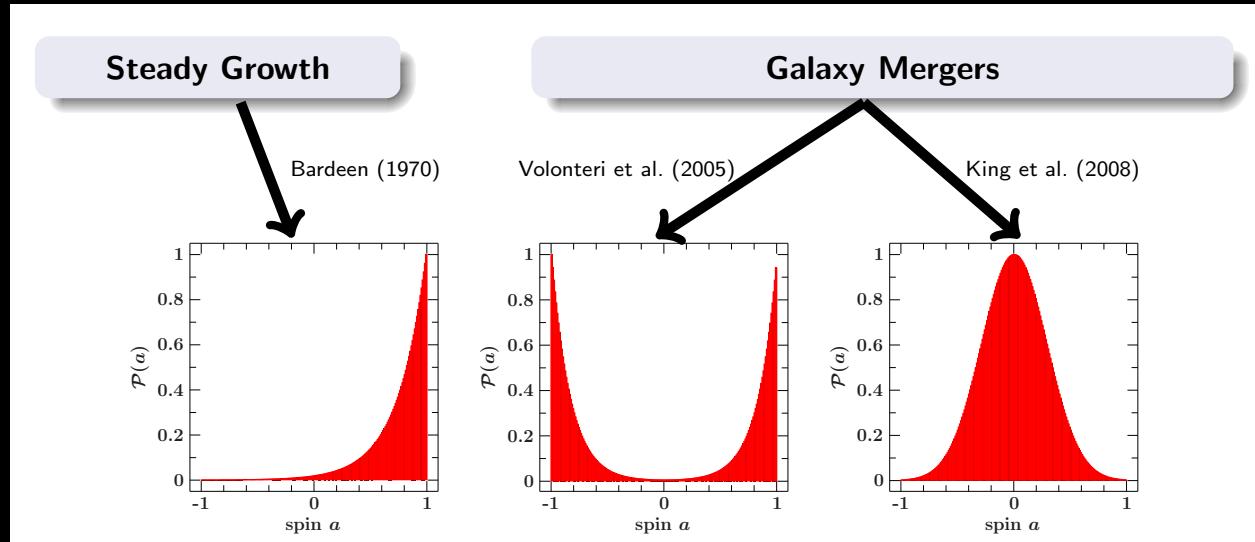

Iron Abundance

# **Measuring the Spin of Black Holes**

# Spin Distribution for SMBHs

The distribution of Spin vs Mass can constrain SMBH formation models (Steady Growth/Galaxy Mergers)

Reynolds (2014), Vasudevan et al. (2016)

Possible observational biases:

- Radiative efficiency scales as  $\sim 1/r$ , which favors high spin detections.
- Also, high spin and low coronae enhances the reflection fraction.

# Measuring Spins in BHs

- BH spins are not always easy to measure. BHs provide better signal but there are still discrepancies.
- Results often depend on the quality of the data, but also on the quality of the observer ;)

Compilation from Krawczynski (2018)

# **The Evolution of the Corona and the Accretion Disk**

# Coronal Geometry

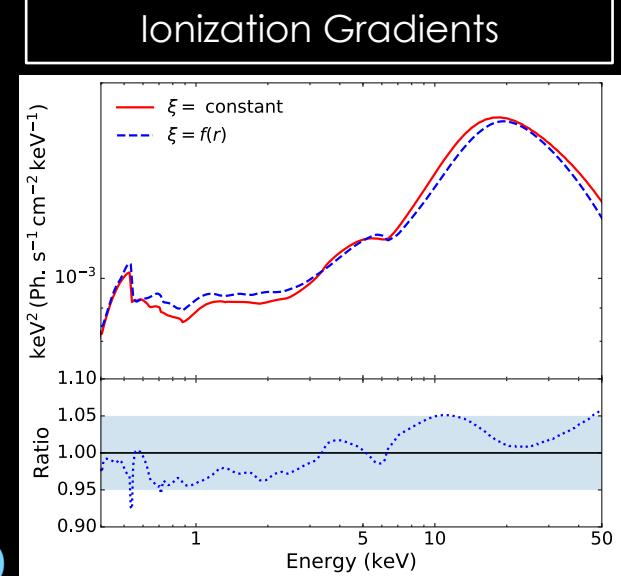

Non-Static and Extended Corona

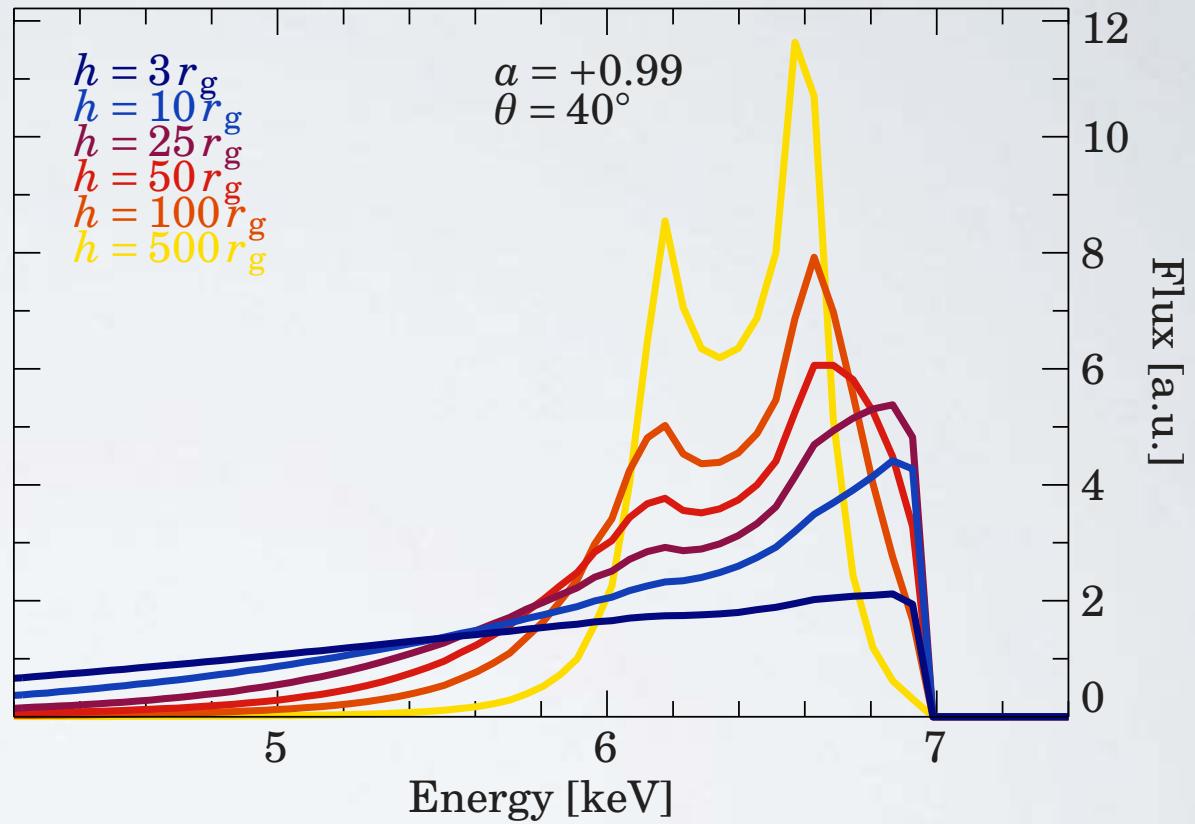

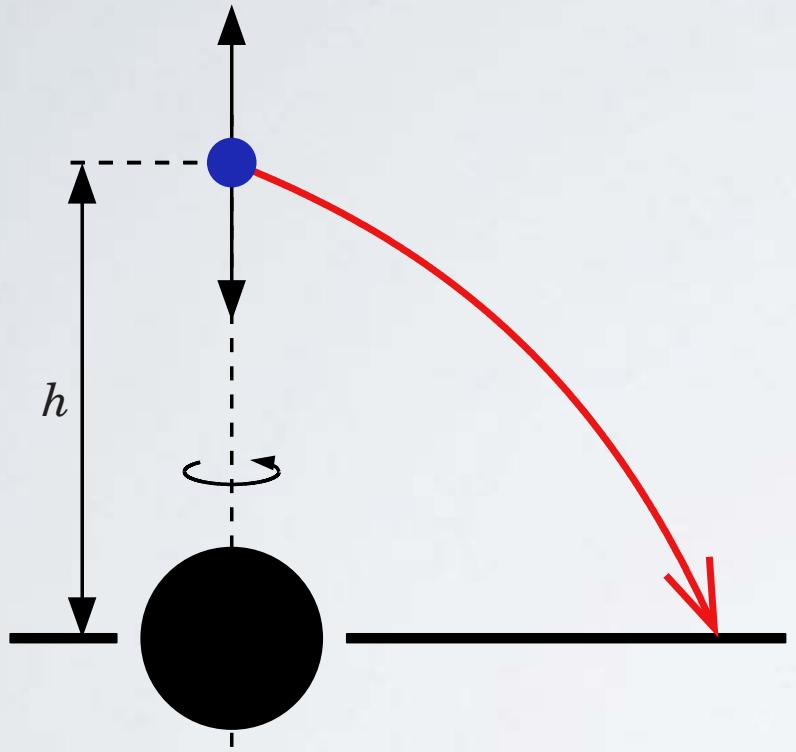

Wilkins et al. (2016)

Svoboda et al. (2012)  
Kammoun et al. (2019)

# Diagnostic Tool: Geometry

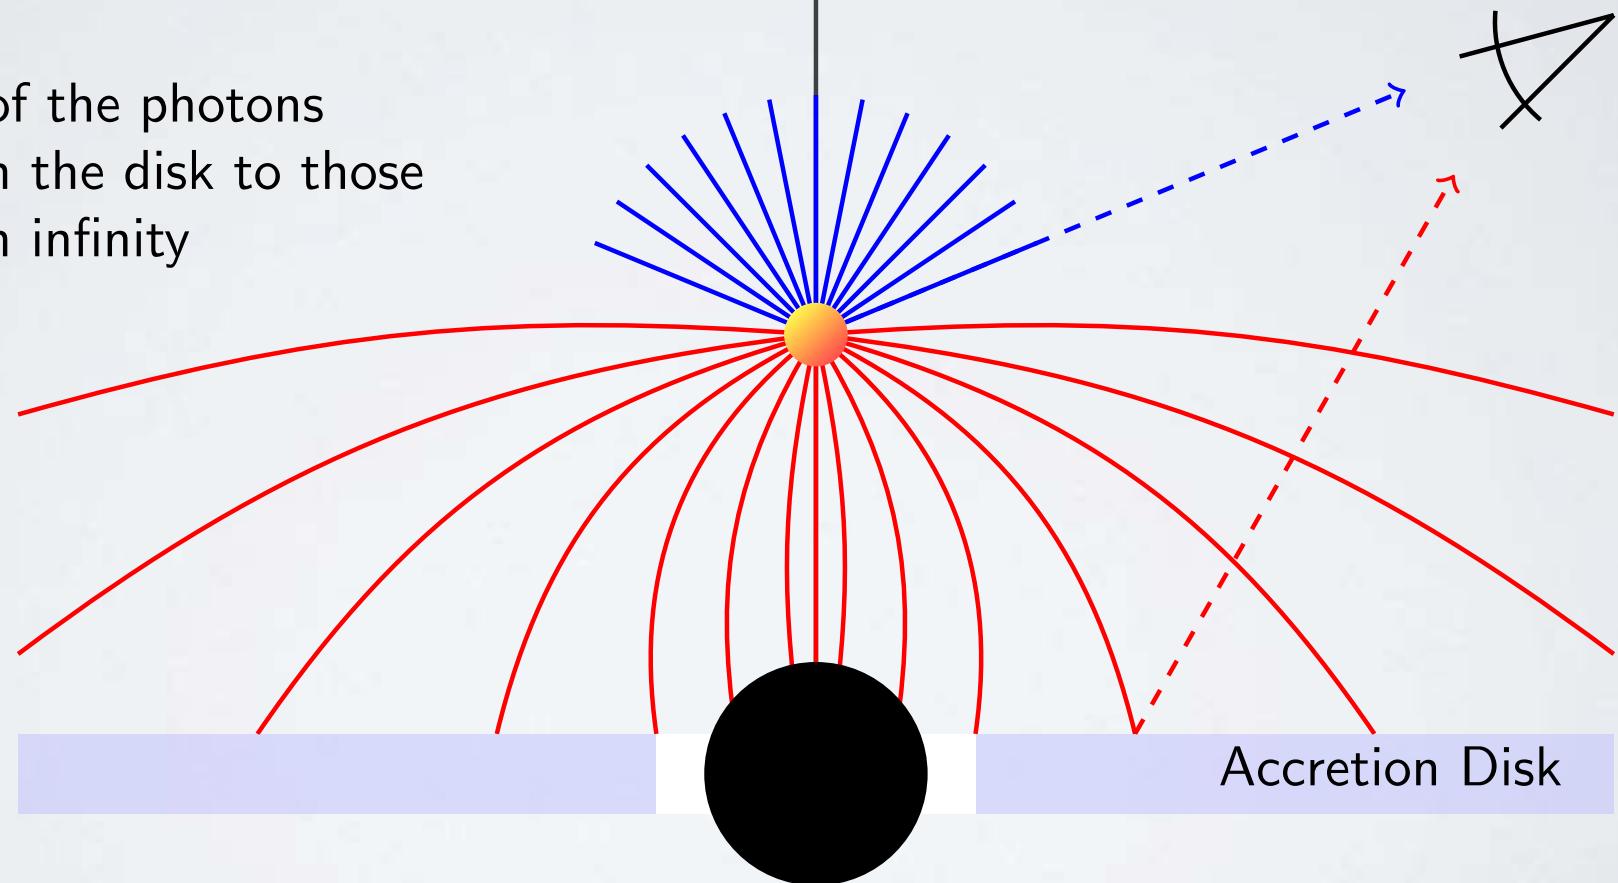

Probe **geometry** and **location** of the primary source  
Low high implies enhanced irradiation of the inner regions

# Light Bending Effects

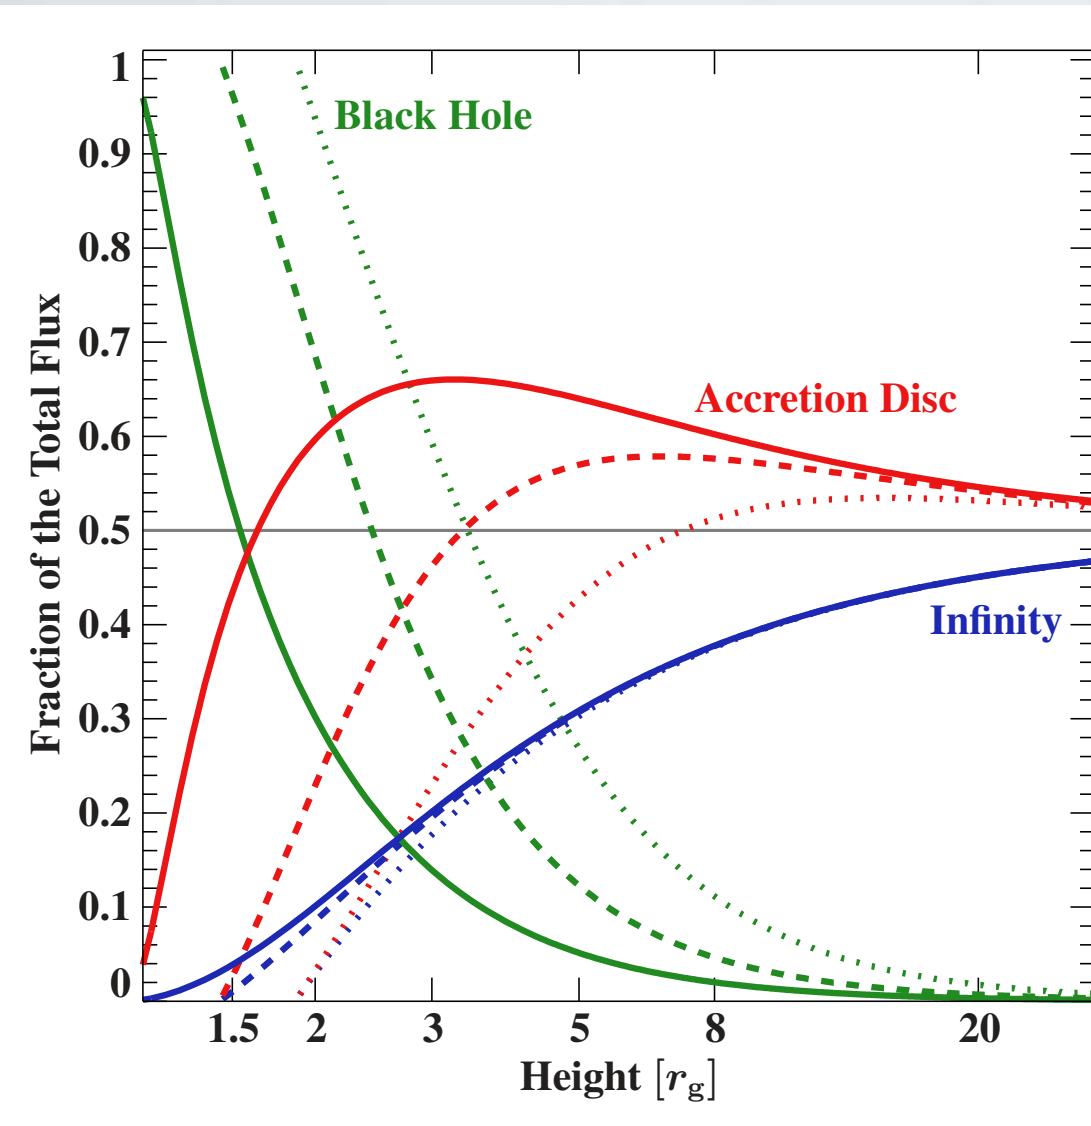

$$R_f = \frac{F_{AD}}{F_\infty}$$

Fraction of the photons  
that reach the disk to those  
that reach infinity

$$R_f > 1$$

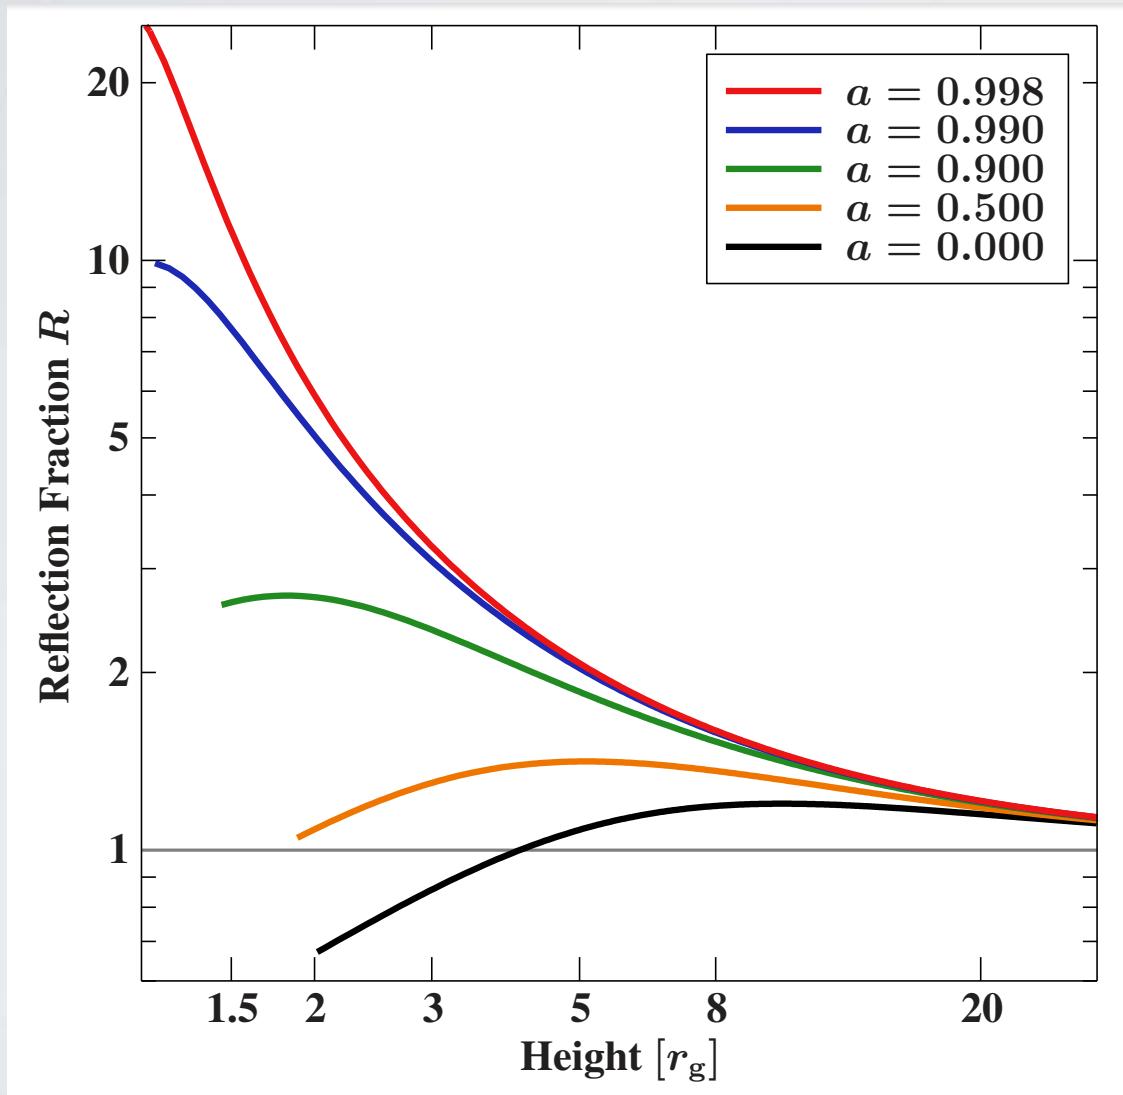

# The Reflection Fraction

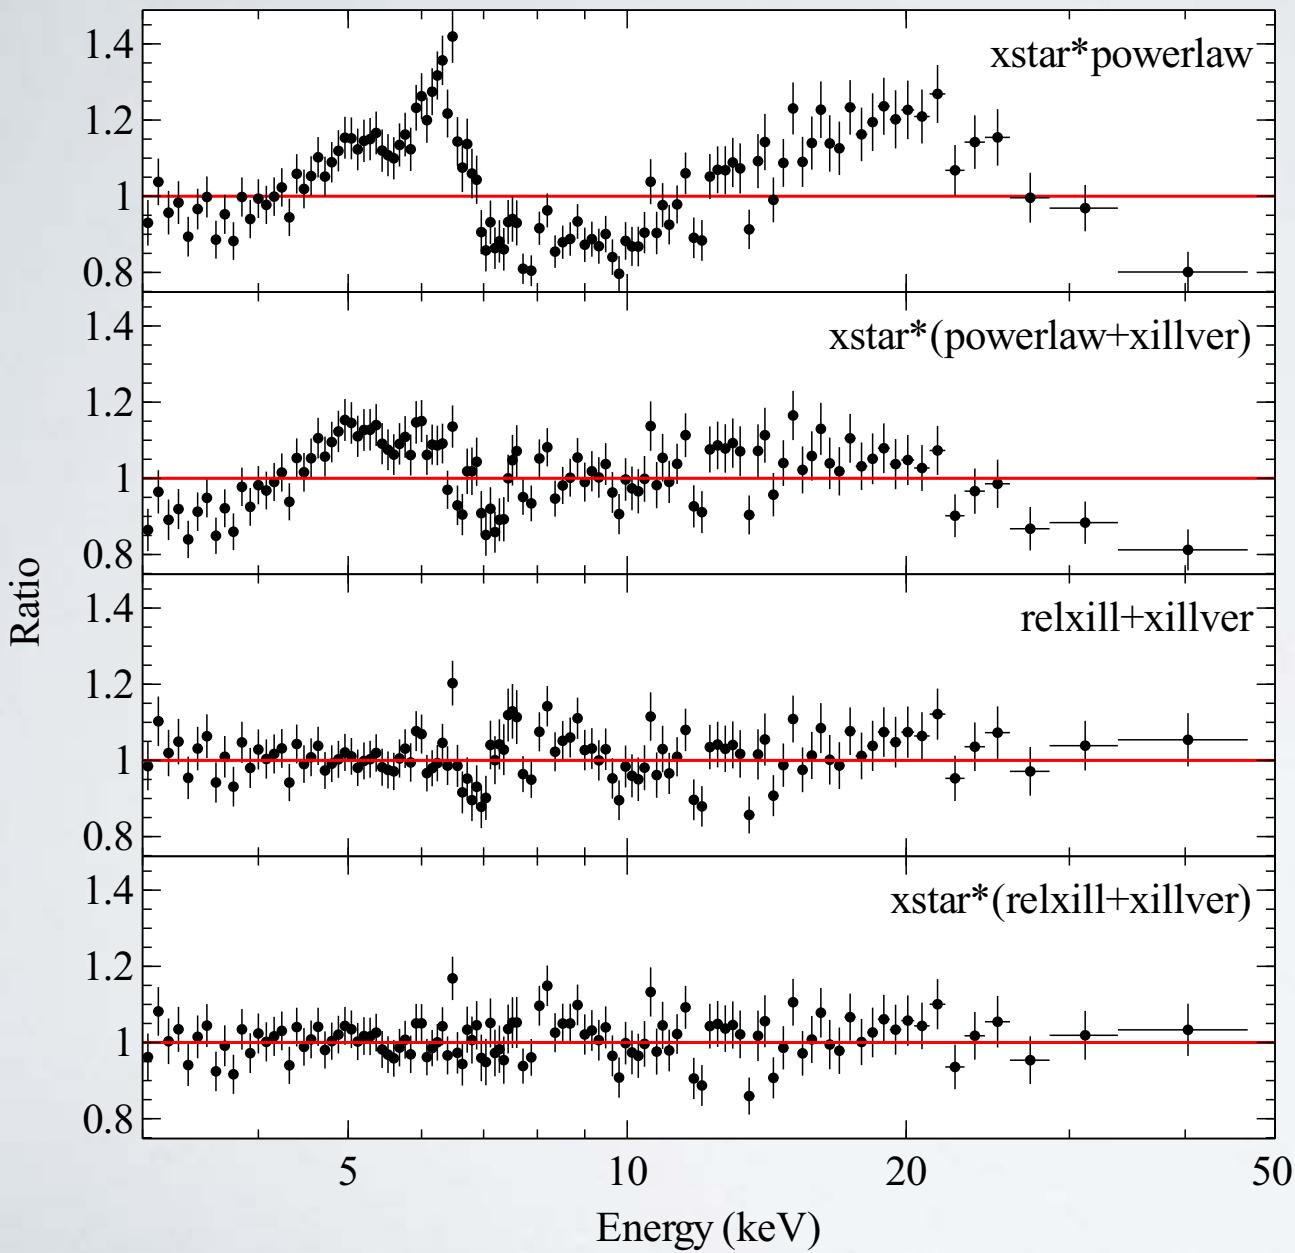

Photons from the corona can reach the observer, hit the accretion disk, or get lost in the black hole

# The Reflection Fraction

The reflection fraction is controlled by the spin, inner radius, and the height of the X-ray source

# Extreme Reflection in Mrk 335

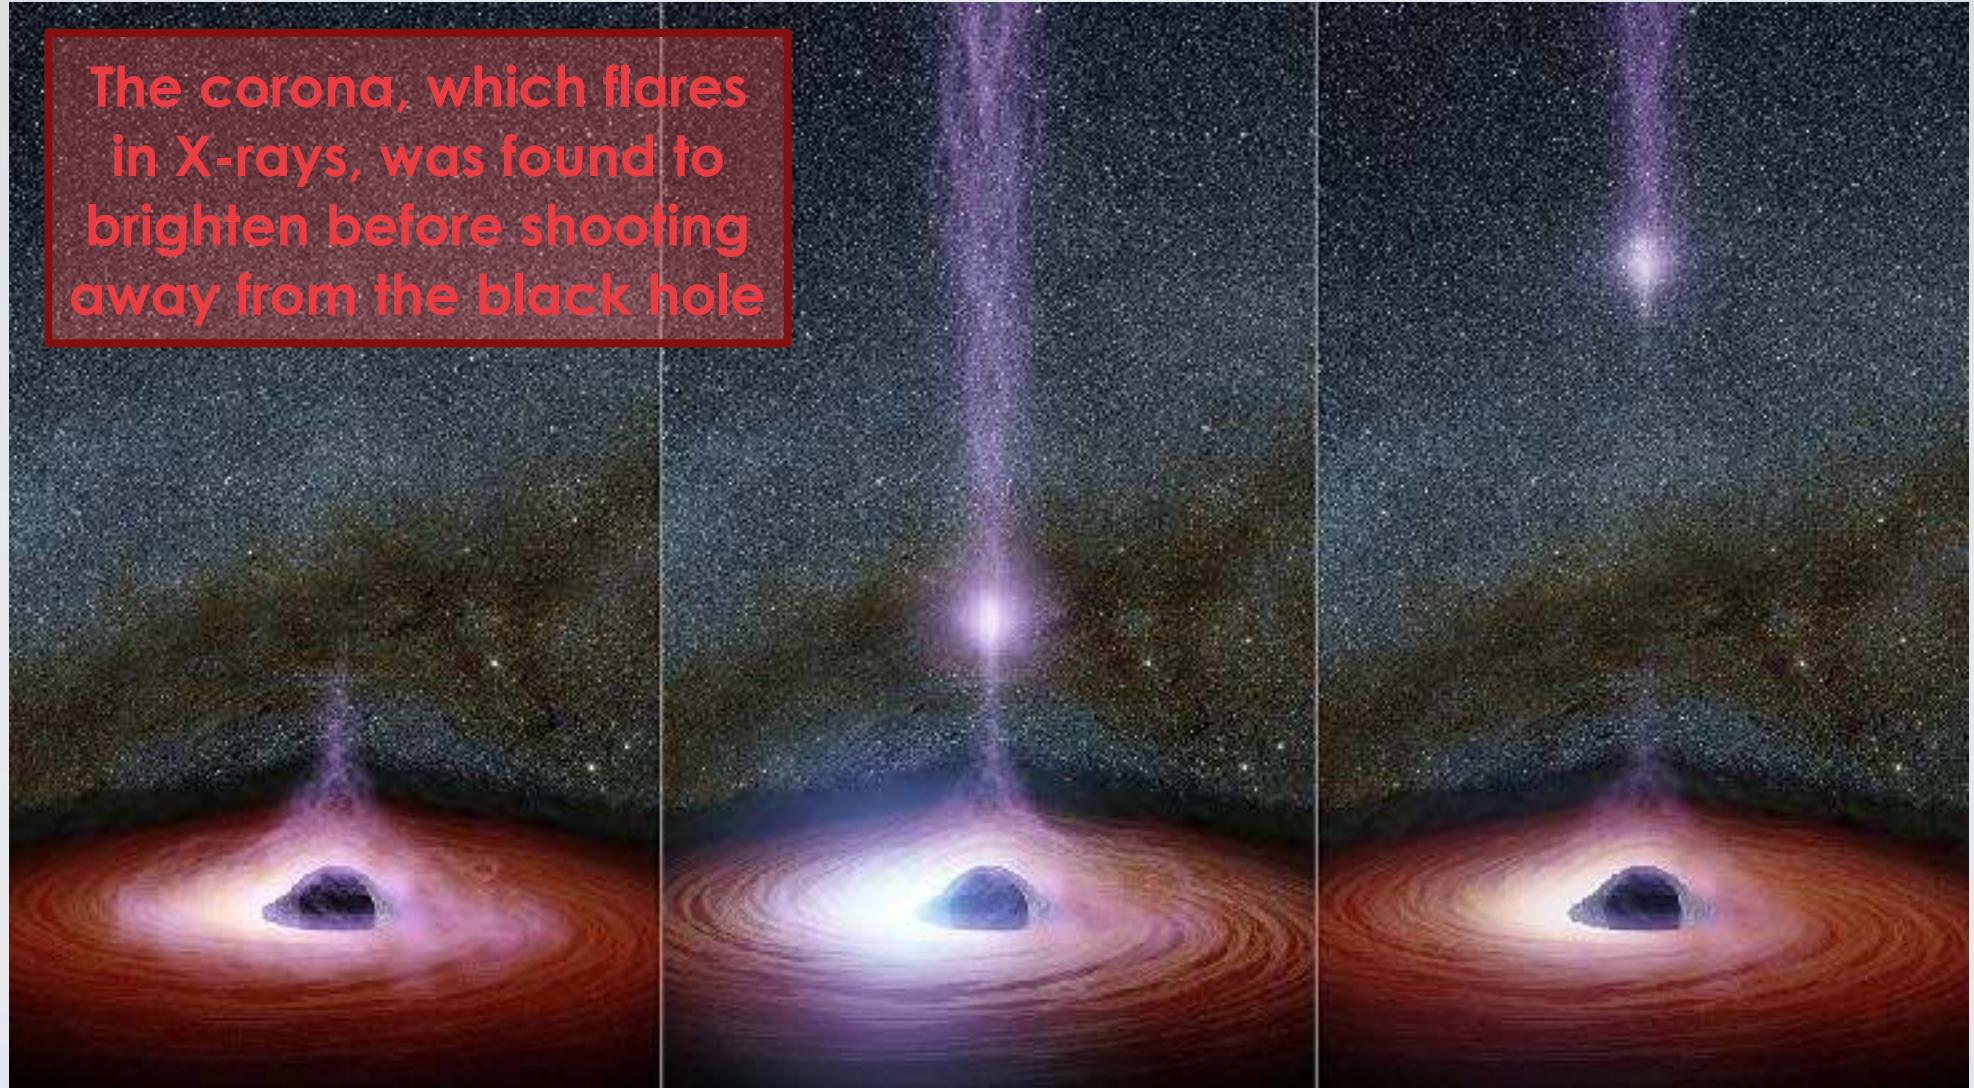

Relativistic effects are observed within just 2 gravitational radii of the event of horizon!  
( $R_g = GM/c^2$ )

Rapidly-spinning black hole  
( $a=0.9$  at 3-sigma confidence)

Powerlaw: continuum Emission  
XSTAR: warm absorber  
XILLVER: distant reflection  
RELXILL: relativistic reflection

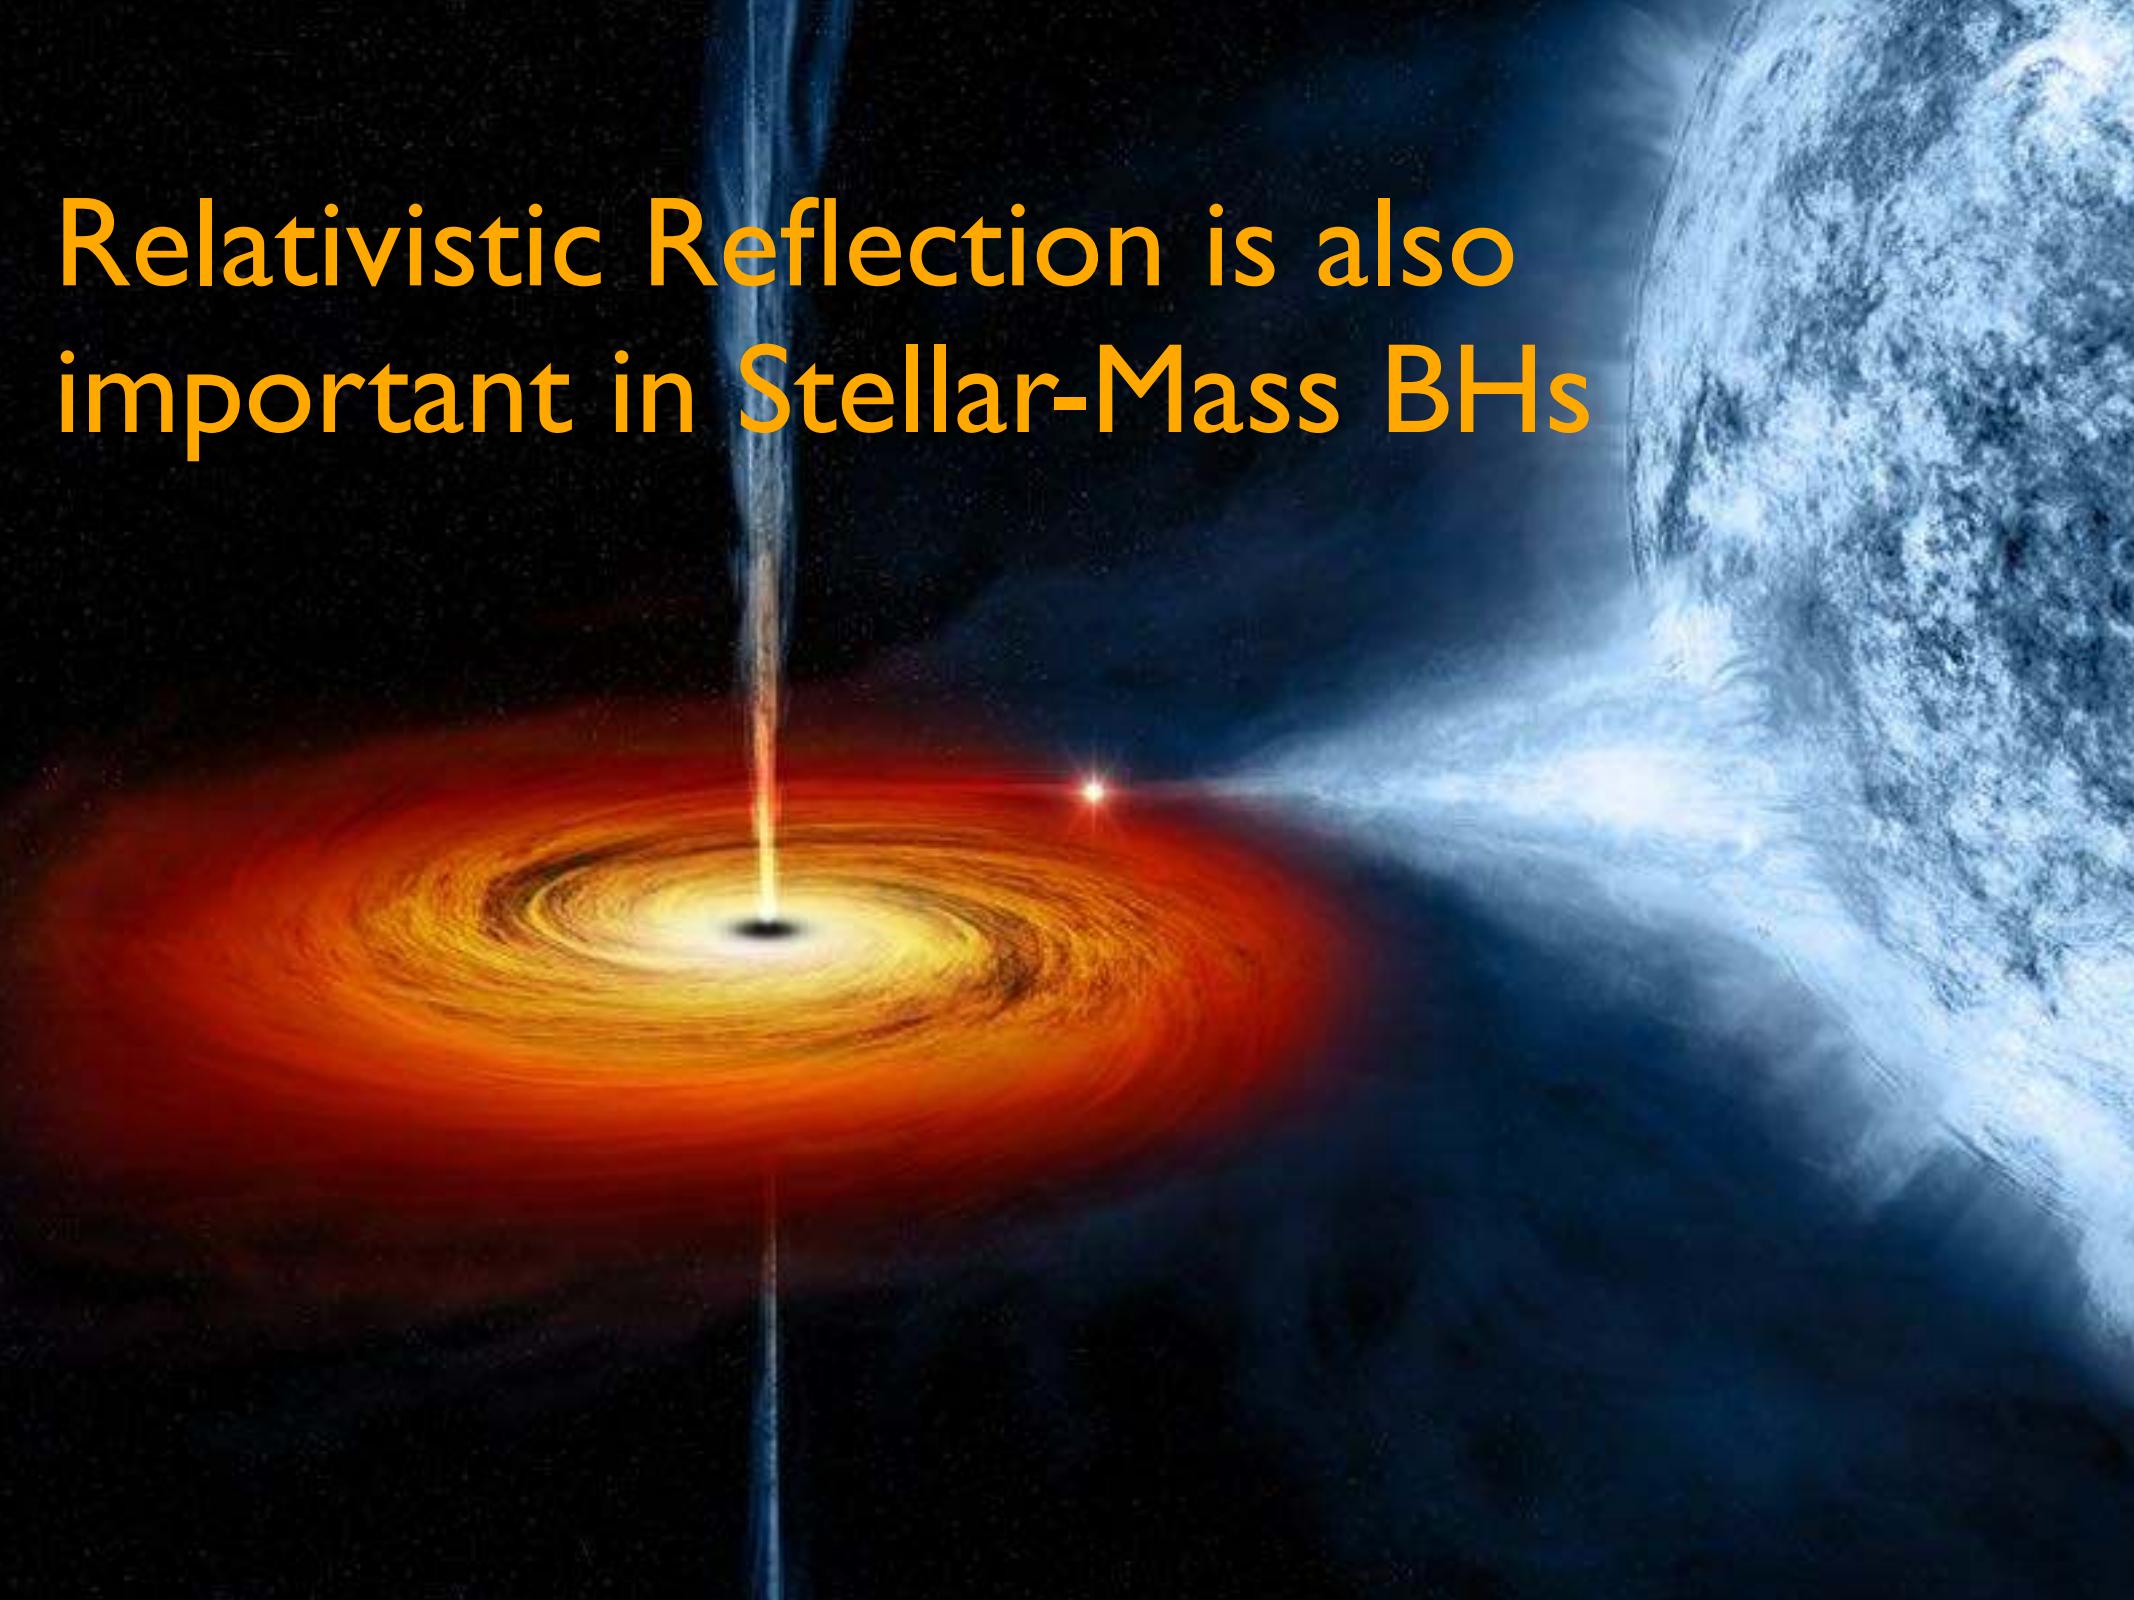

100 ks NuSTAR observation  
(Parker et al. 2014)

# Extreme Reflection in Mrk 335

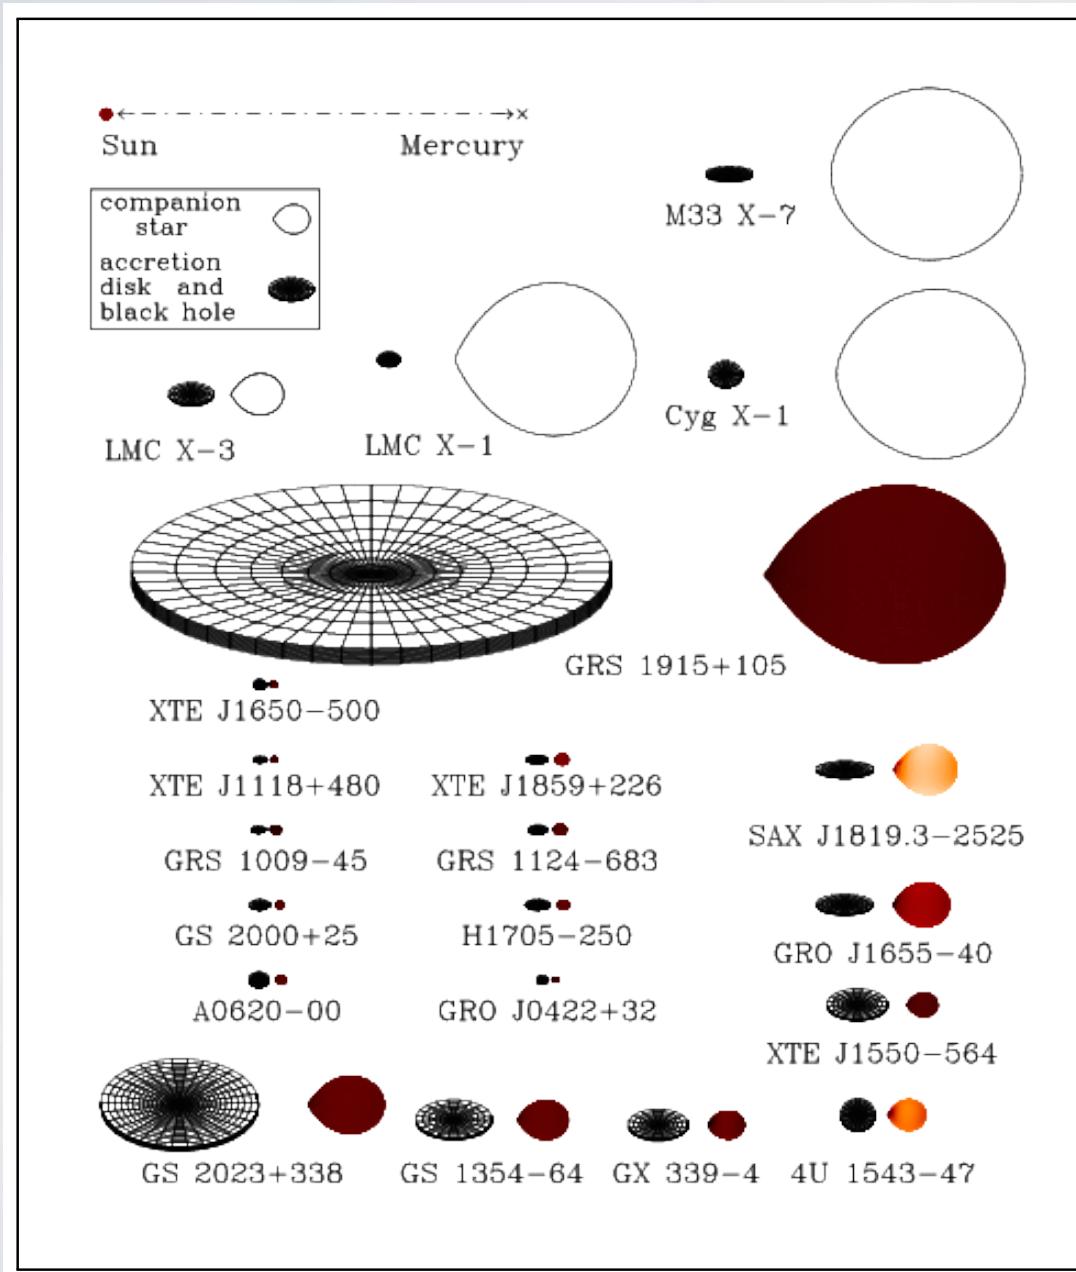

Wilkins et al. (2015)

Relativistic Reflection is also  
important in Stellar-Mass BHs

# Black Hole Binaries (BHs)

- Stellar Masses ( $\sim 5\text{-}30 \text{ M}_{\odot}$ )
- Modest variability in human time-scales
- Many are transient in nature
- They flare in X-rays increasing their luminosity by a billion fold
- An outburst can last from weeks to months
- AU-scale persistent jets and parsec-scale ballistic jets
- X-ray Quasi-Periodic Oscillations (QPOs) (0.01-450 Hz)
- Very distinct spectral states: hard/intermediate/soft**

(Figure courtesy of Jerome Oroz)

# RXTE: Rossi X-ray Timing Experiment

Observed hundreds of X-ray sources between December 1995 and January 2012

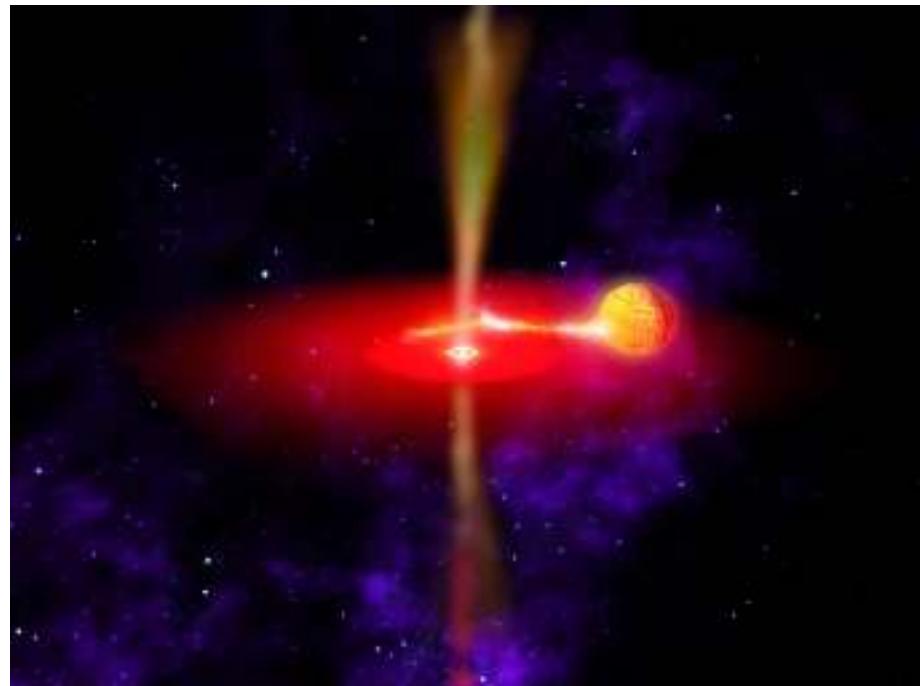

## Proportional Counter Array (PCA)

- Energy range: 2 - 60 keV
- Energy resolution: < 18% at 6 keV
- Time resolution: 1 microsec
- Detectors: 5 proportional counters
- Collecting area: 6500 square cm
- Layers: 1 Propane veto; 3 Xenon, each split into two; 1 Xenon veto layer
- Sensitivity: 0.1 mCrab

PCA made ~110,000 pointed observations collecting ~295 Msec of data

# The Prototypical BH Binary GX 339-4

Hynes+03:

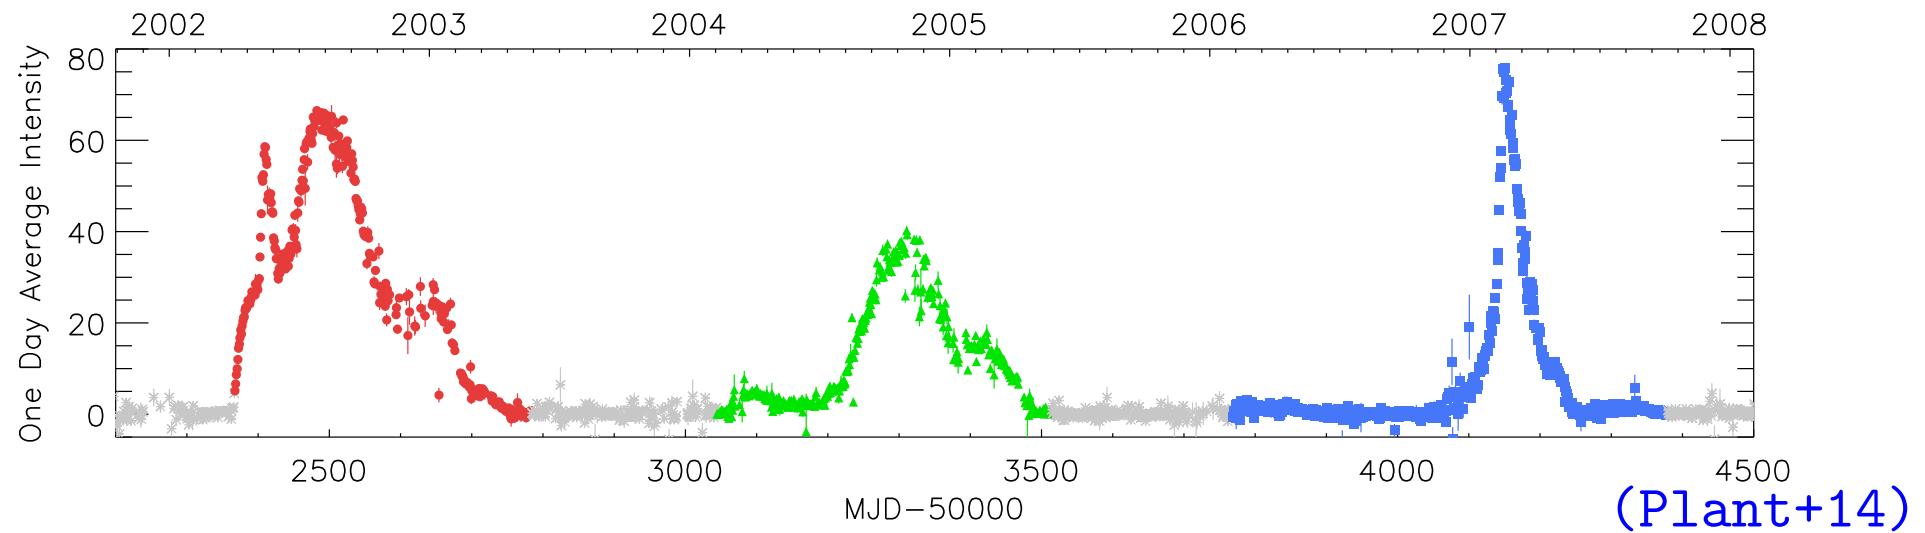

$$f(M) = 5.8 \pm 0.5 M_{\odot}$$

Kolehmainen+Done10:

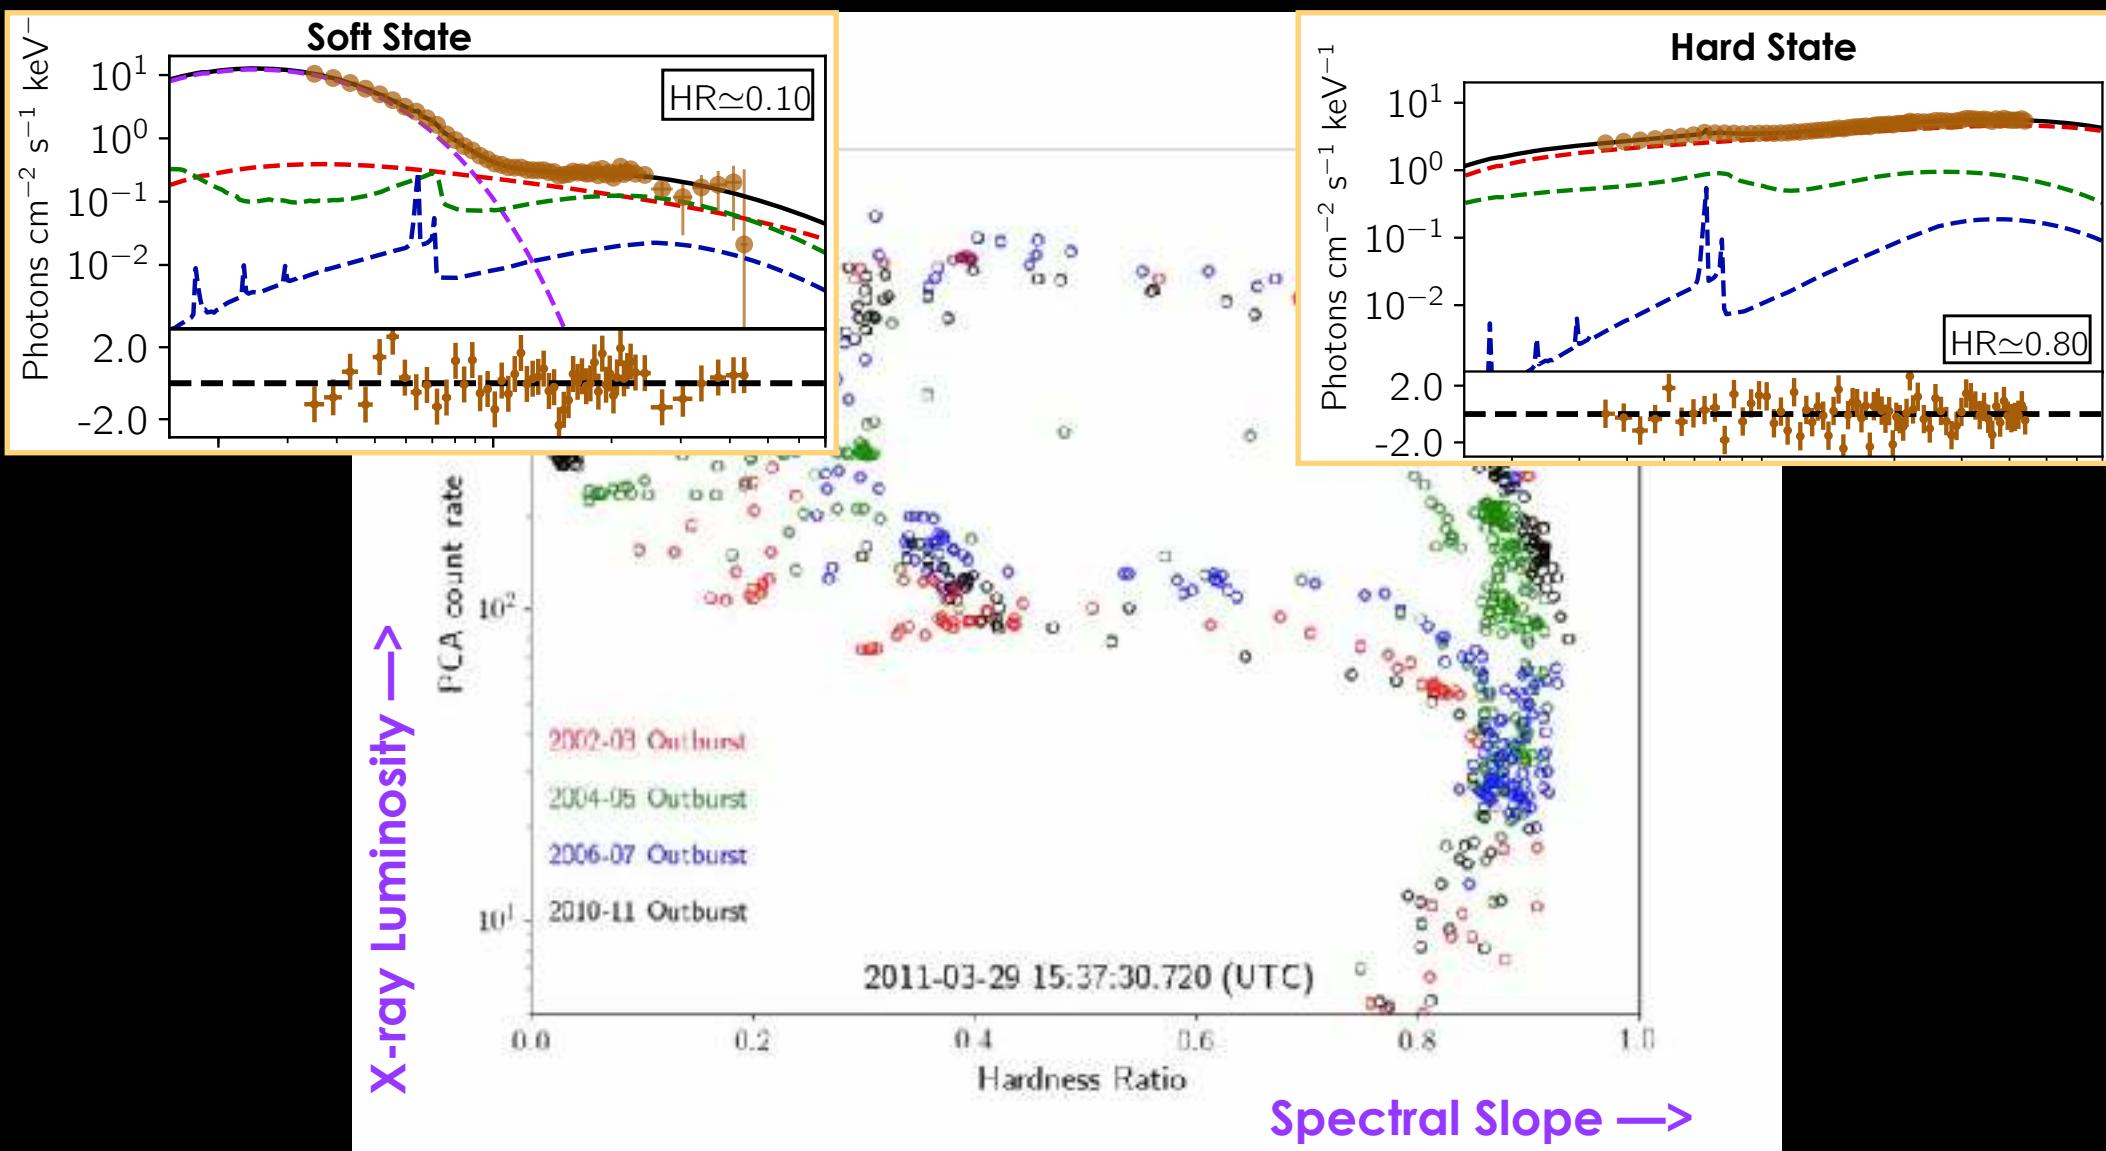

$$D = 6 - 15 \text{ kpc}$$

$$M = 6.2 - 15 M_{\odot}$$

$$20^\circ < i < 70^\circ$$

# BHBs in Outburst— Cyg X-1

# The Hard State of GX 339-4

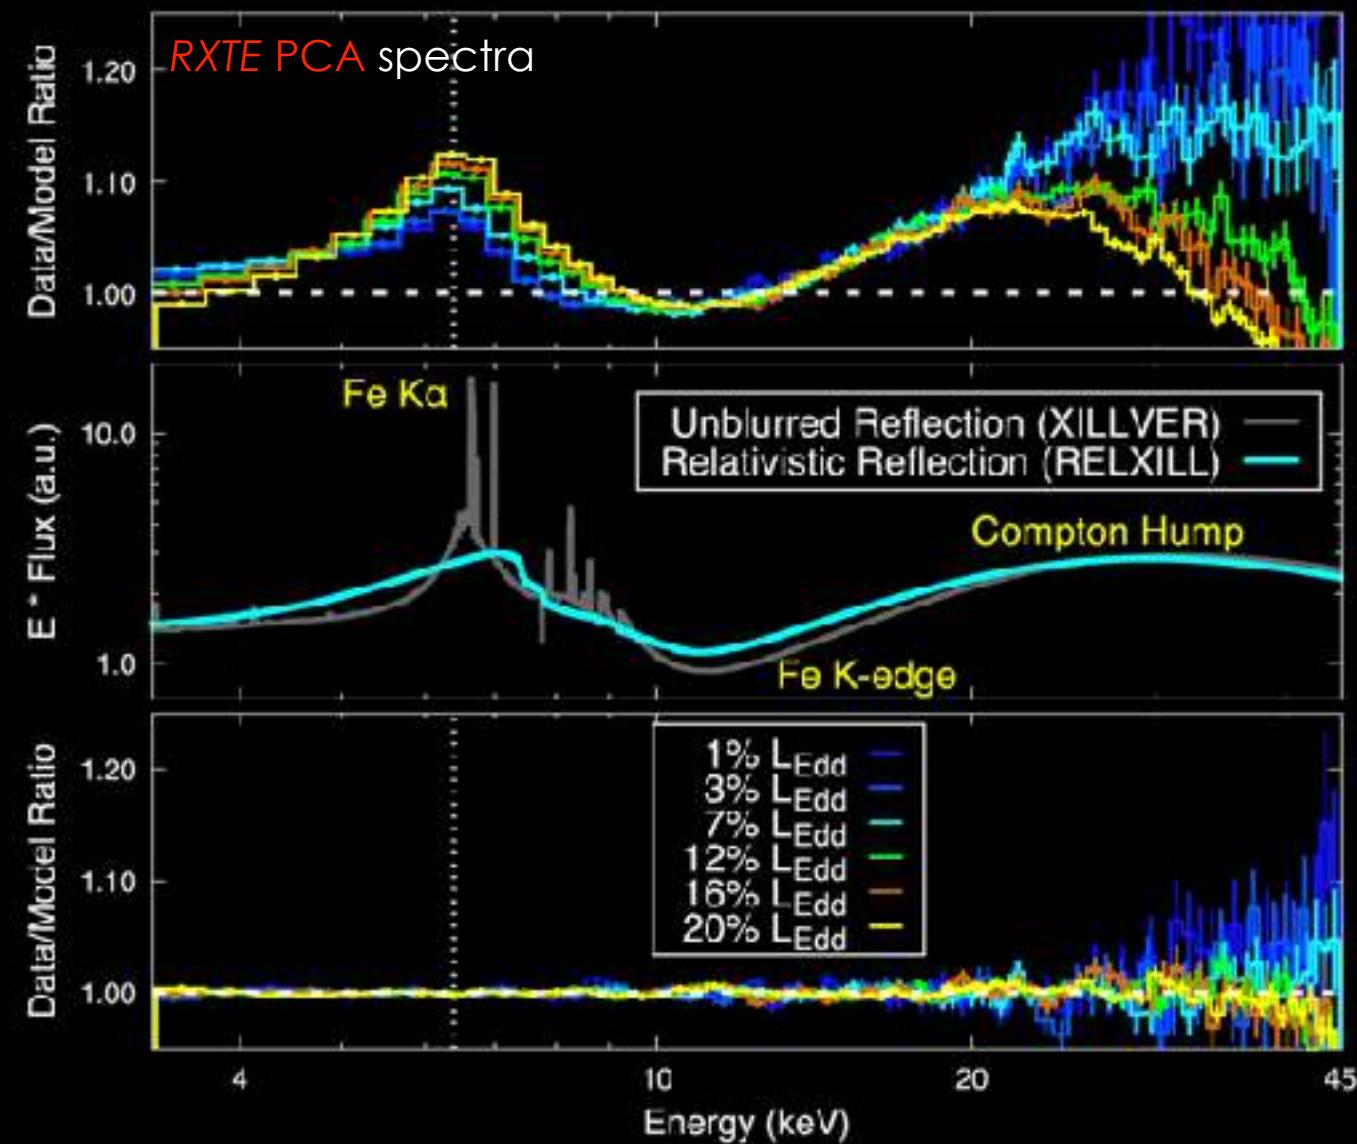

# Disk and Corona Evolution

Relativistic reflection fits of the black hole binary system **GX 339—4**

$a = 0.95 \pm 0.04$   
 $i = 48 \pm 1 \text{ deg}$   
Fe abundance **5x Solar**

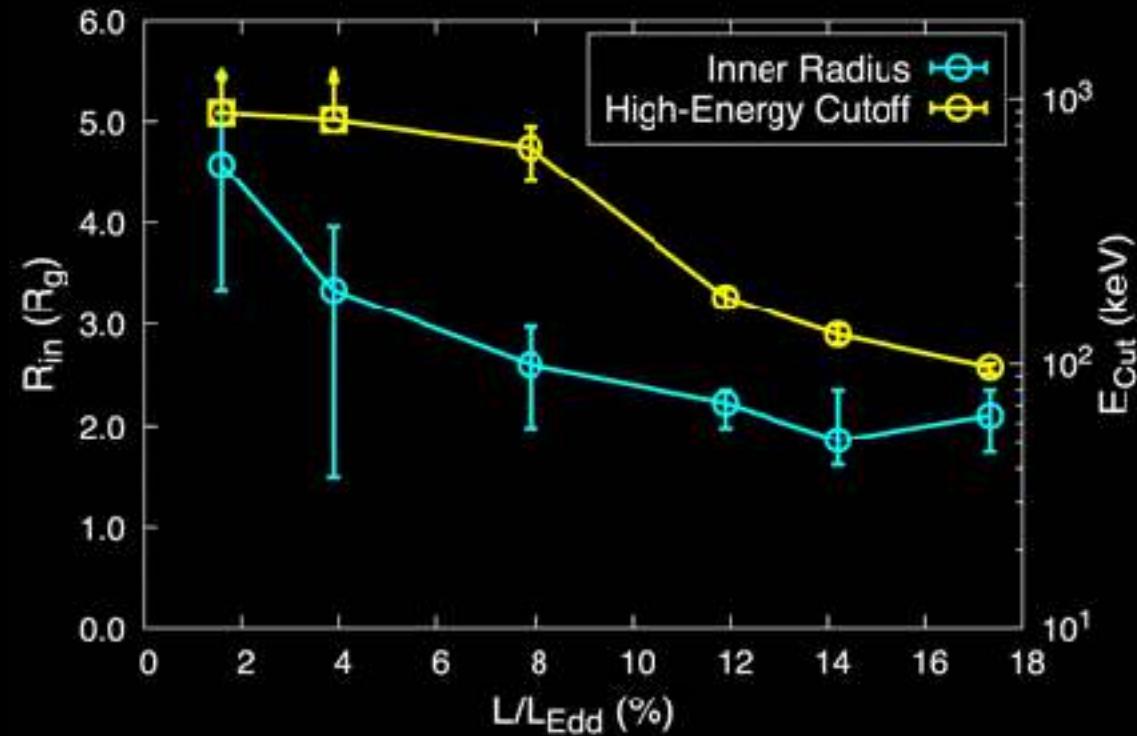

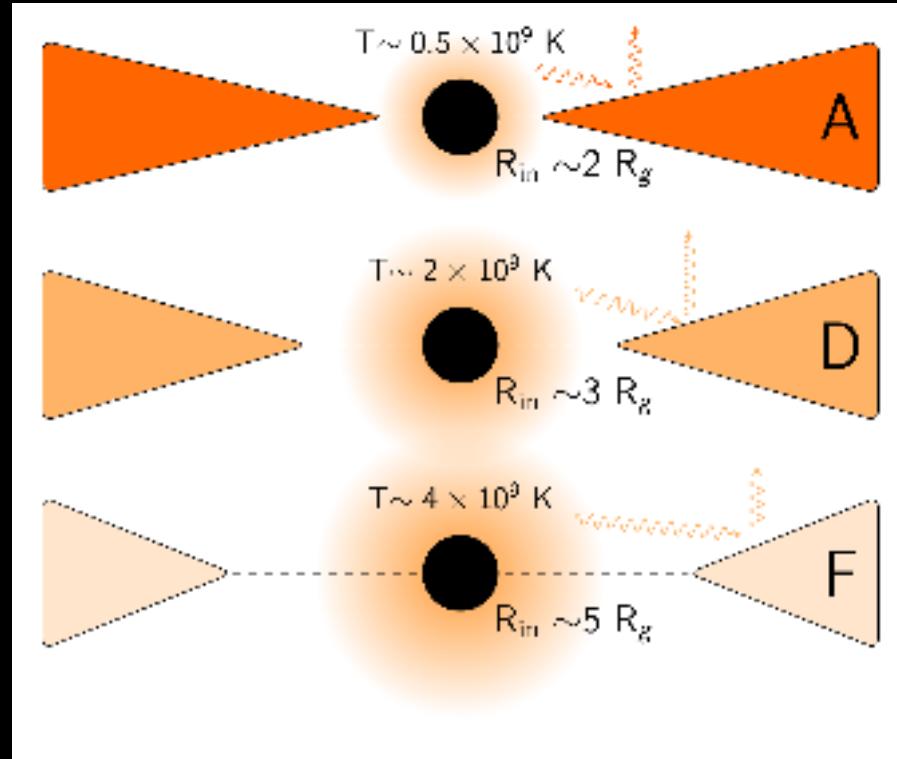

García et al. (2015b)

Total of 77 million counts  
in six **RXTE PCA** spectra  
(3–45 keV)

García et al. (2015b)

# Disk and Corona Evolution

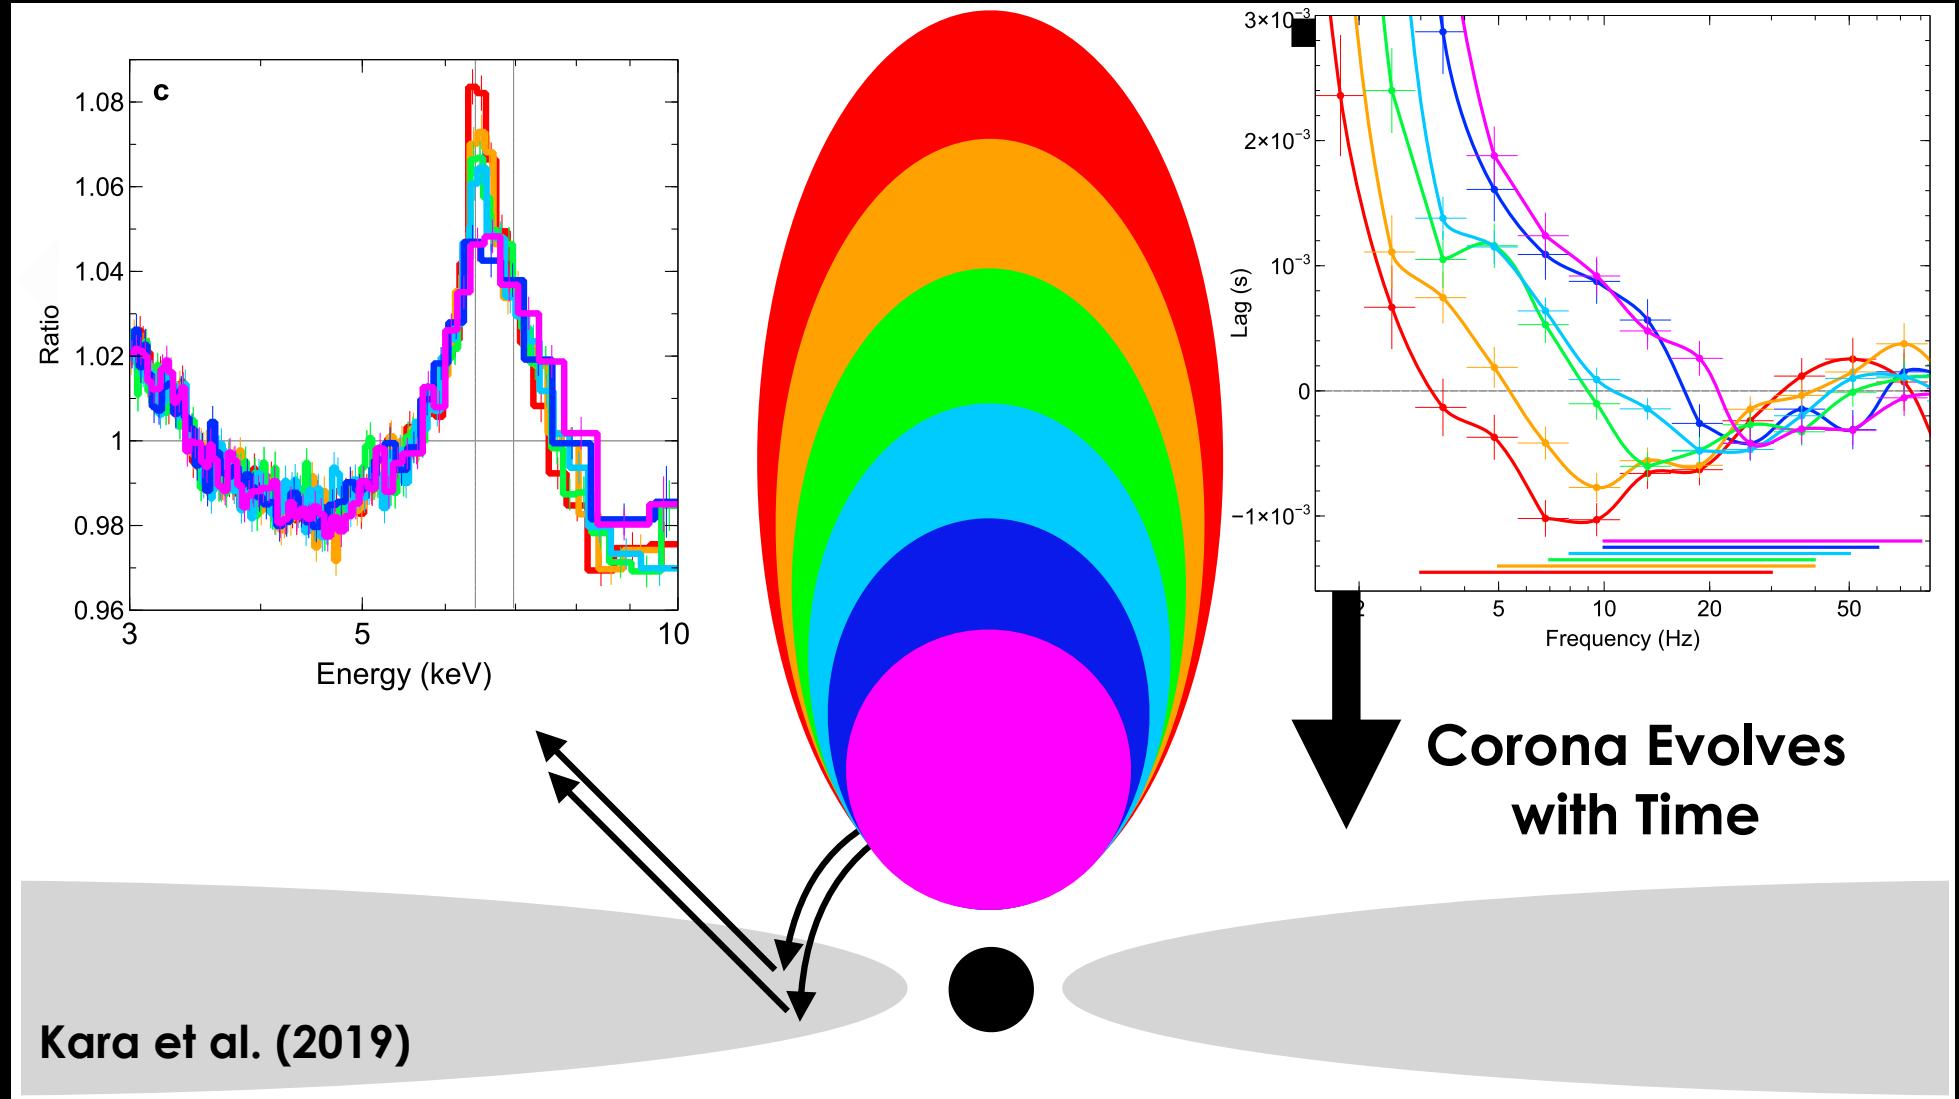

For a 10 Solar-mass BH:  
Delta  $R_{in}$   $\sim 45$  km

- Luminosity increases by  $\sim 20x$
- $R_{in}$  decreases from a few to ISCO
- Coronal Temp decreases by  $10x$
- Yet, continuum slope remains the same ( $\Gamma \sim 1.6$ )... why?

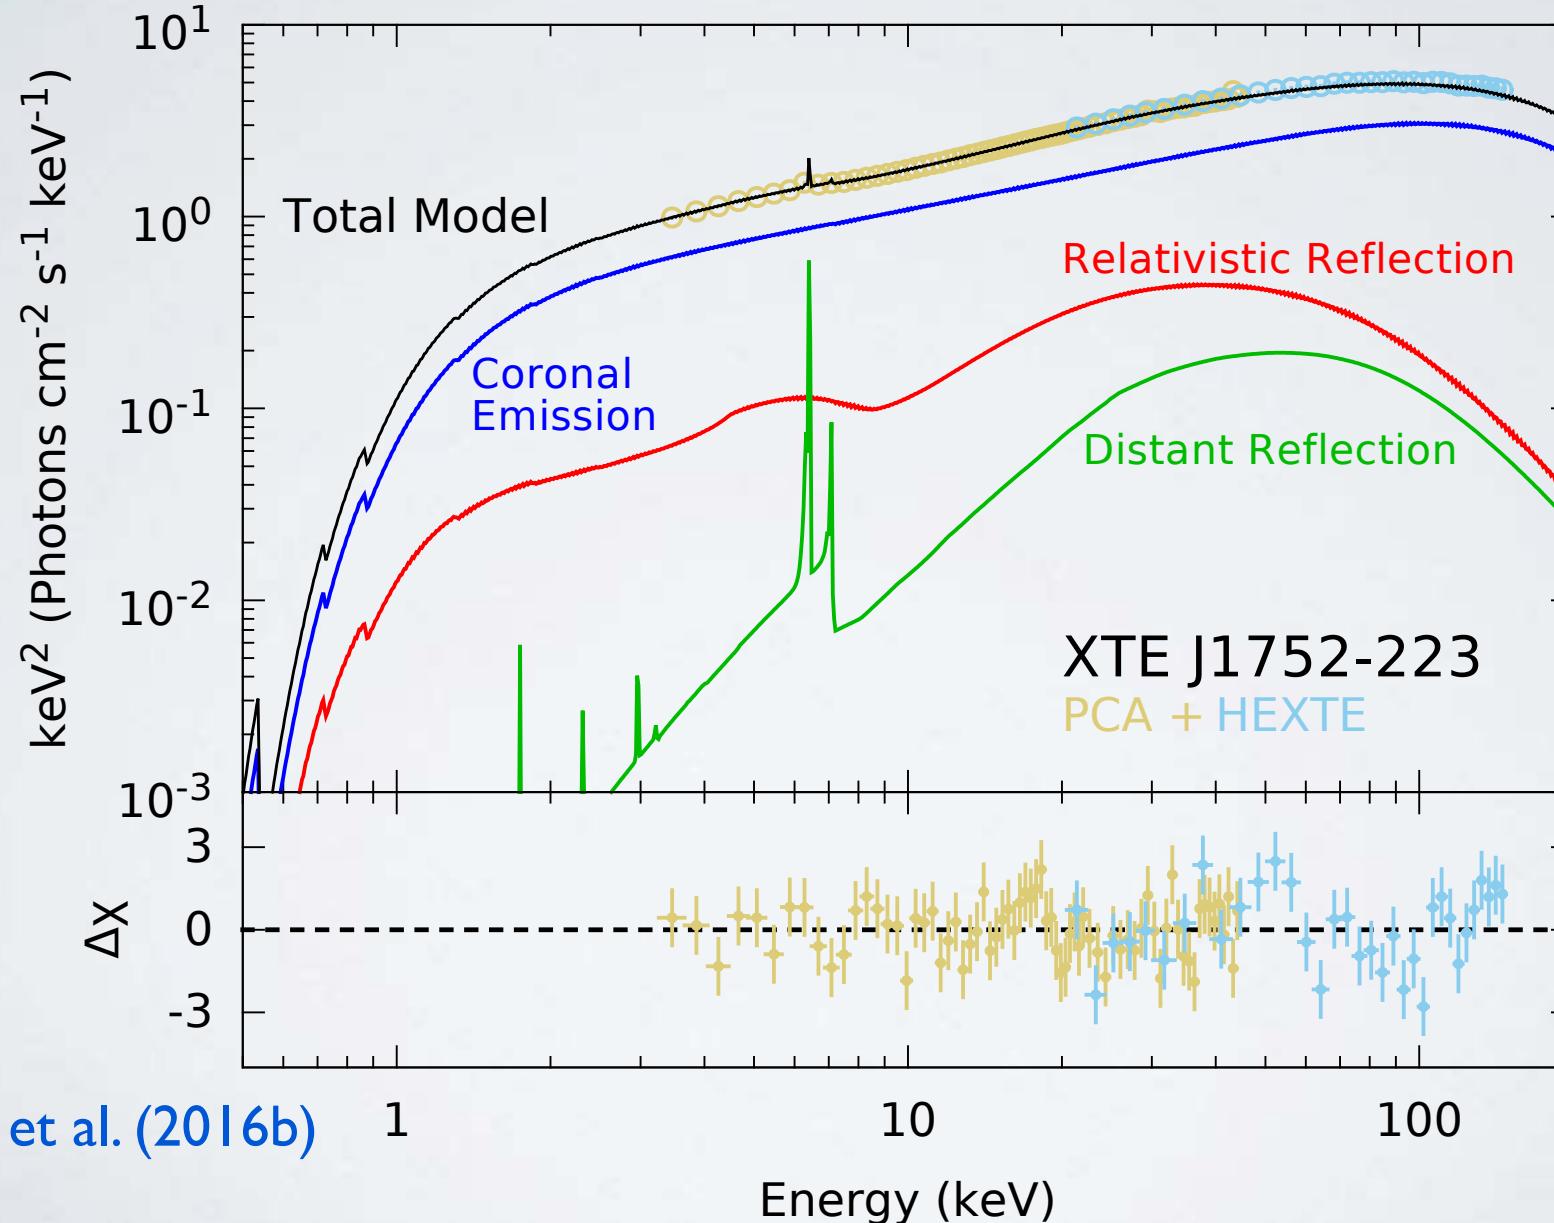

# Disk and Corona Evolution

New Black Hole Binary **MAXI J1820+70** as seen by **NICER**

# Fits to XTE J1752-223

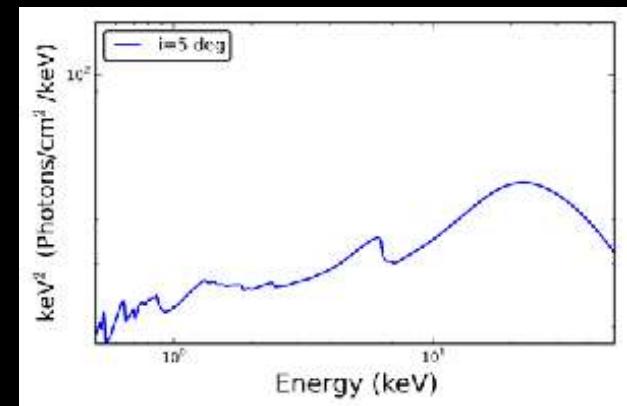

Similarly to GX 339-4, we find a rapidly spinning black hole ( $a^* \sim 0.992$ ), also with super-solar iron abundance ( $A_{Fe} \sim 4$ )

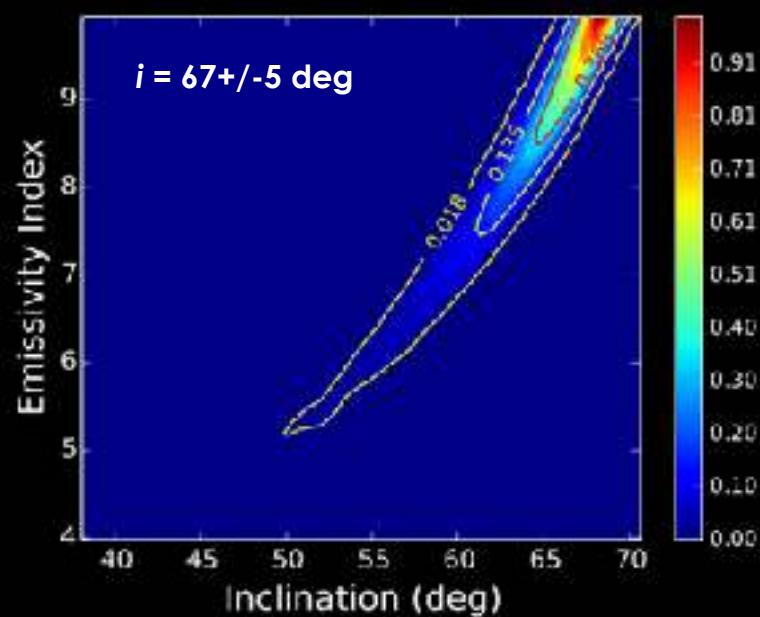

García et al. (2016b)

# Illumination Geometry

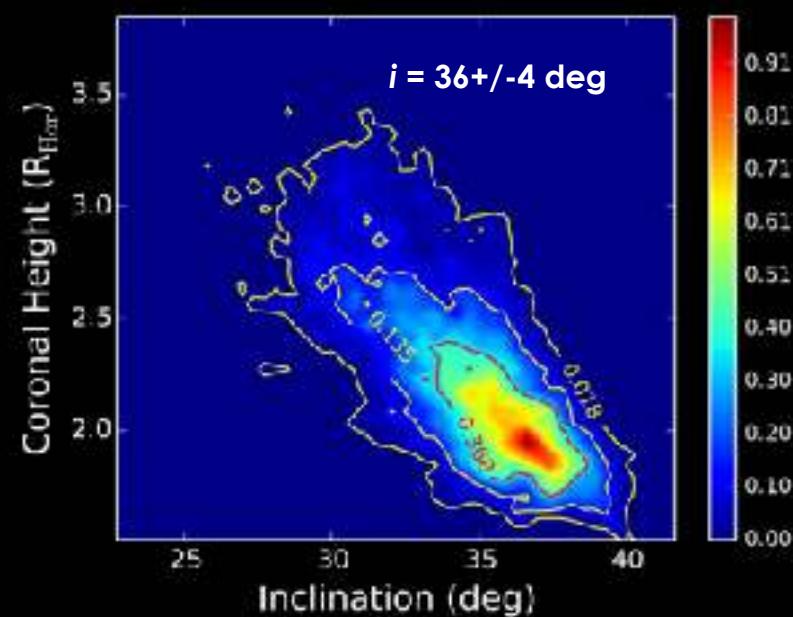

Inner-Disk Inclination

Power-law Emissivity

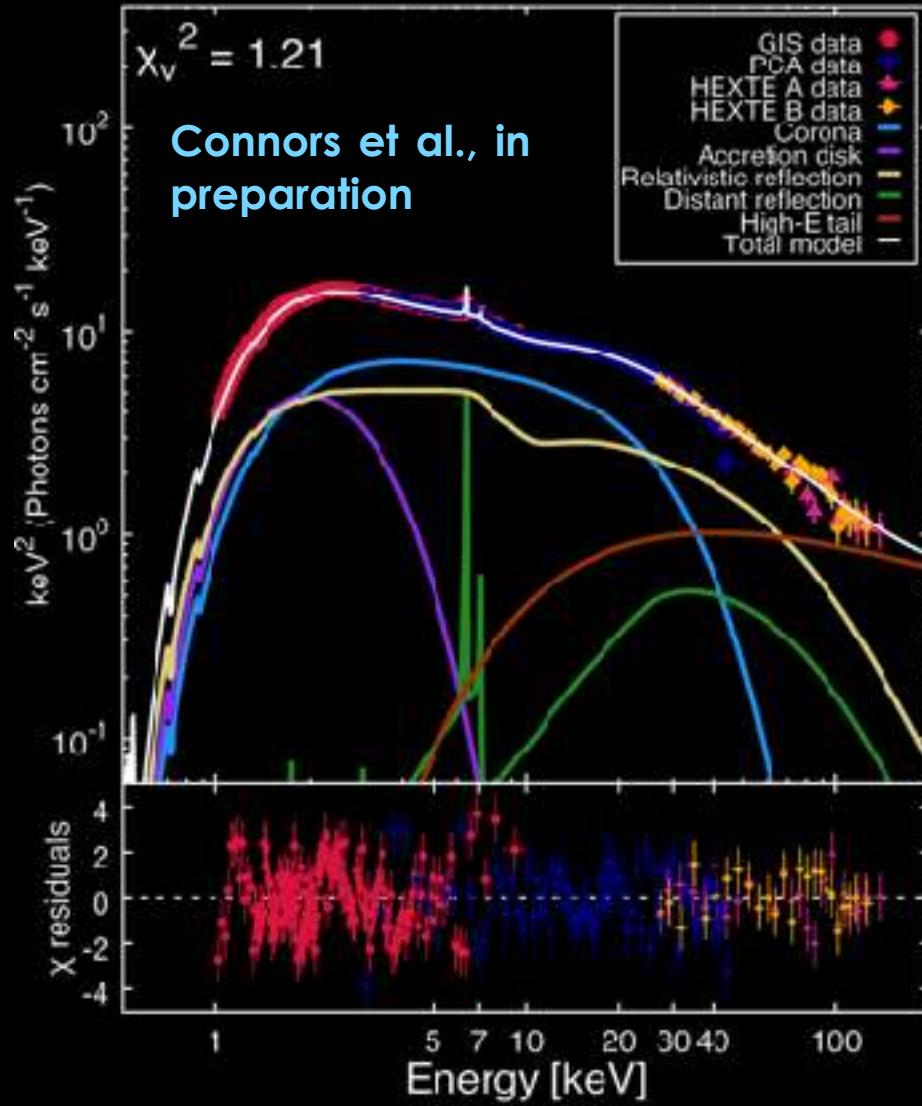

Lamppost Geometry

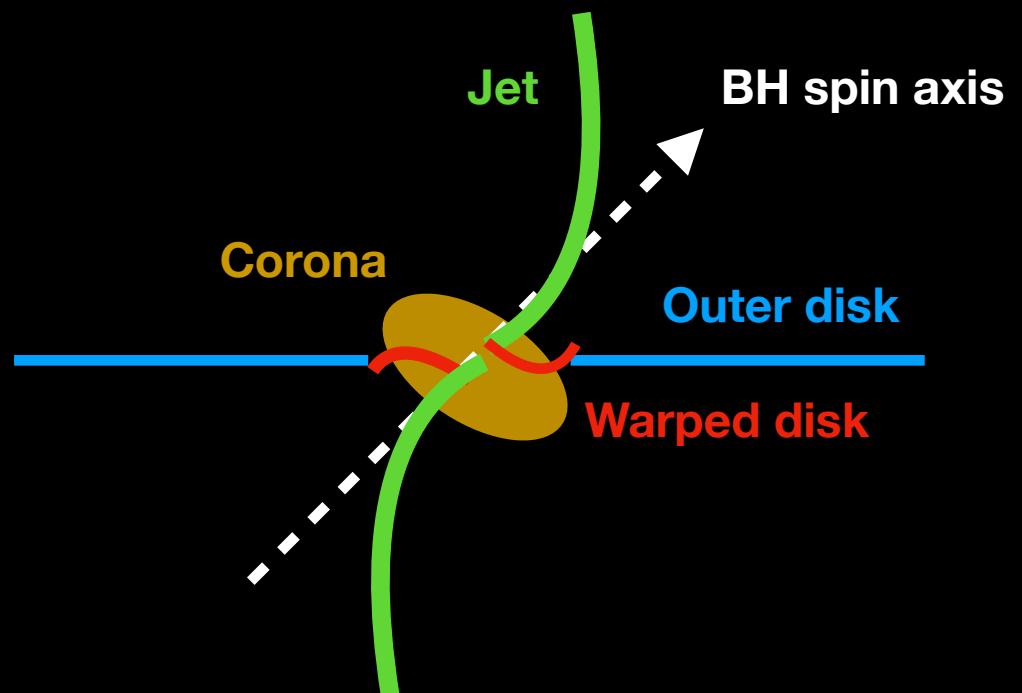

Inclination from the lamppost model consistent with radio jet determinations of  $i < 49 \text{ deg}$  (Miller-Jones et al. 2011).

# XTE J1550-564 - LOW INCLINATION DISK?

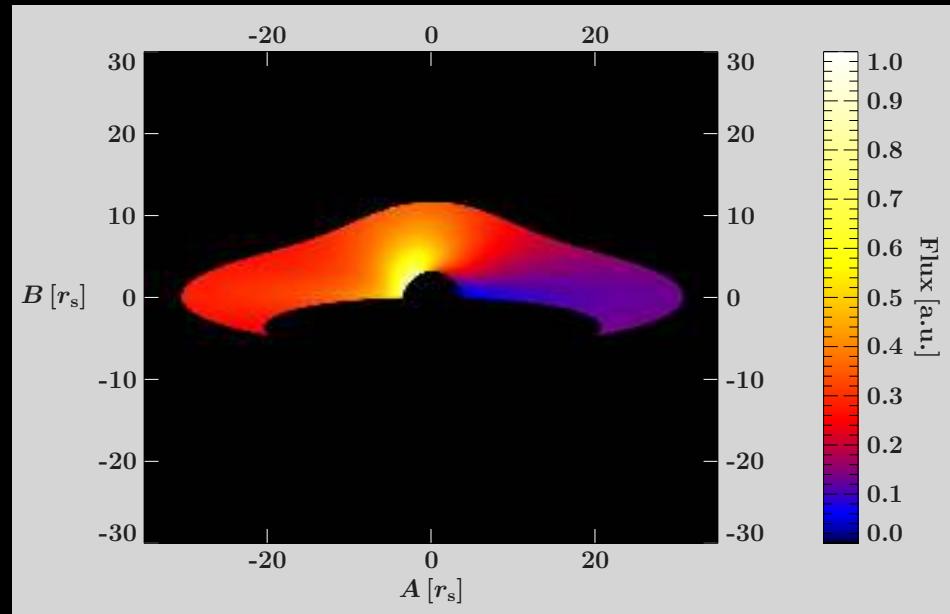

Inclination from reflection modeling inconsistent with radio jet and optical monitoring determinations of the orbital inclination,  $i \sim 40$  deg, as opposed to  $i \sim 75$  deg (Orosz et al. 2011, Steiner et al. 2012).

Possible misaligned inner accretion region?

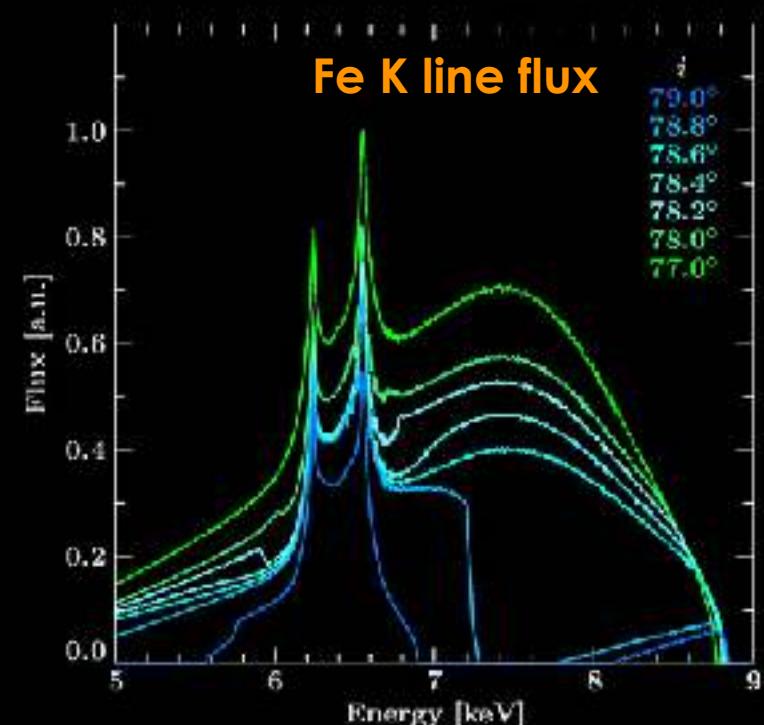

# Irradiation of Flared Disks

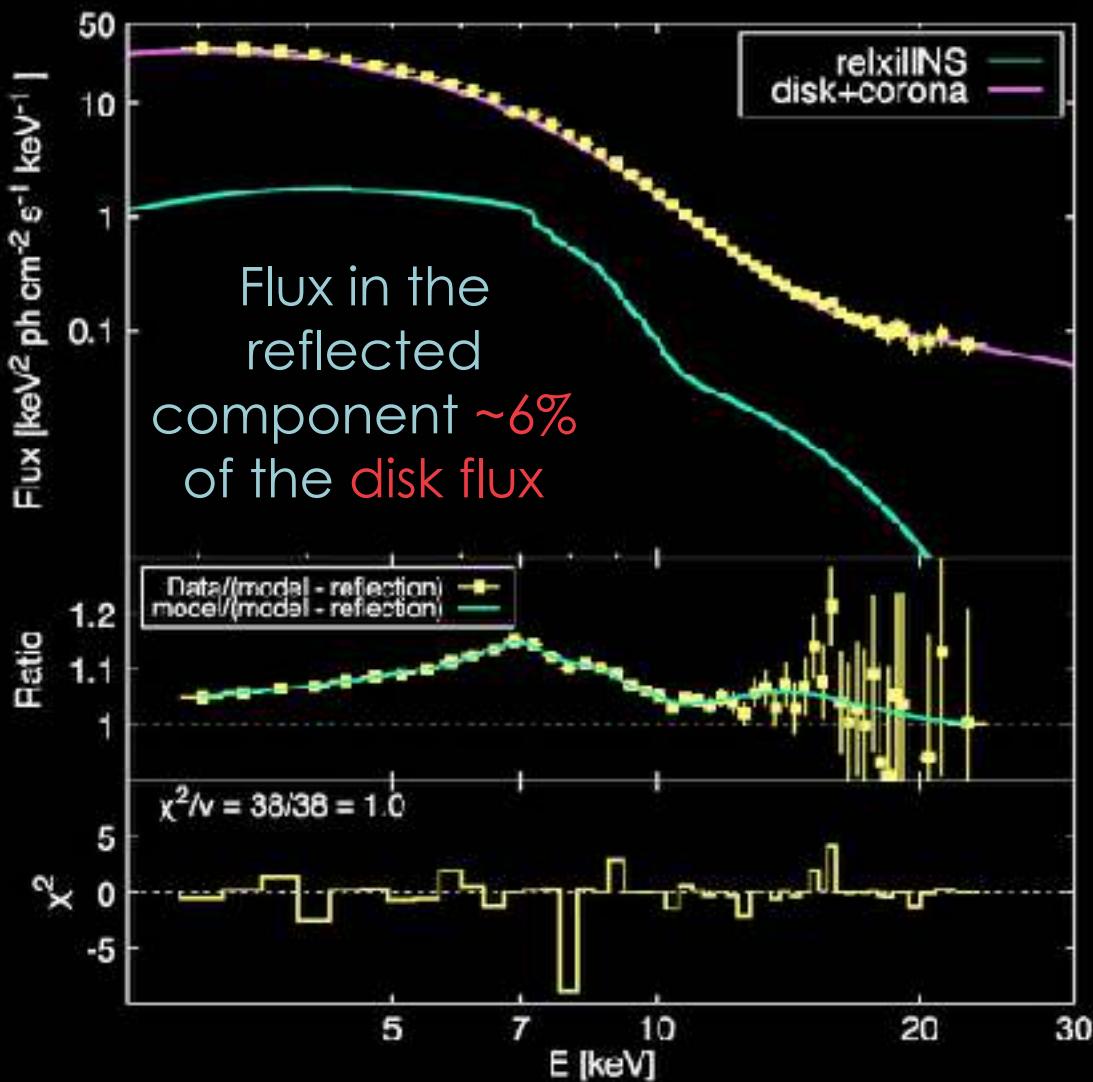

Disk obscuration reduces the blue-wing of the Fe K emission  
→ **Resembles lower inclination!**  
See Taylor & Reynolds (2018)

## Obscuration effects:

Under an inclination of **78.5°**, part of the disk is covered, affecting both the **line profiles** and the **time lags**

# Disk Self Irradiation

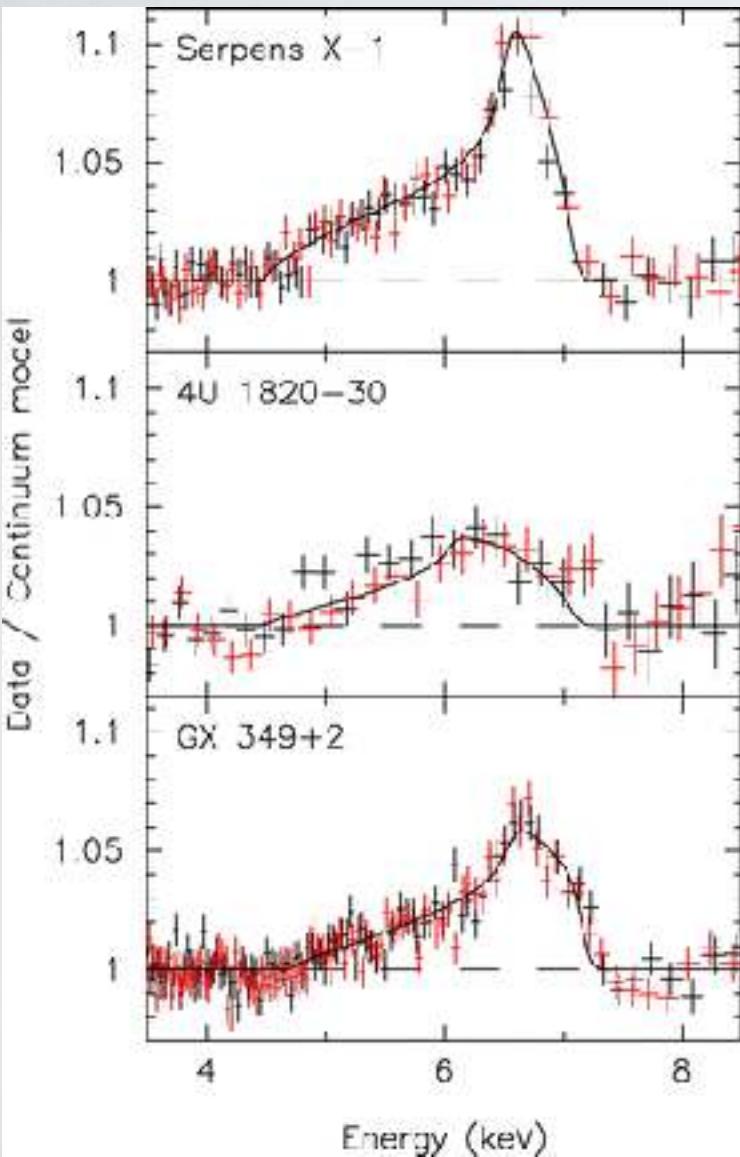

Connors, JG,+20

Radiation Returning to the Disk  
due to GR light bending

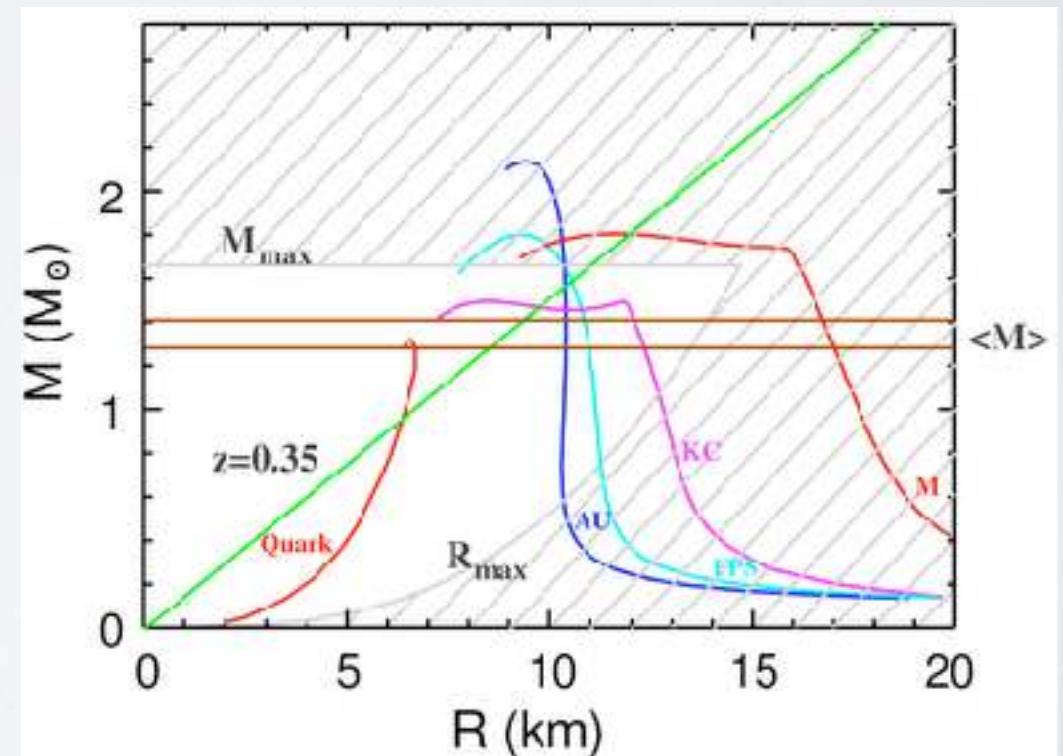

Flux fraction of returned radiation  
consistent with ray tracing  
calculations

# Fe K Reflection in Neutron Stars

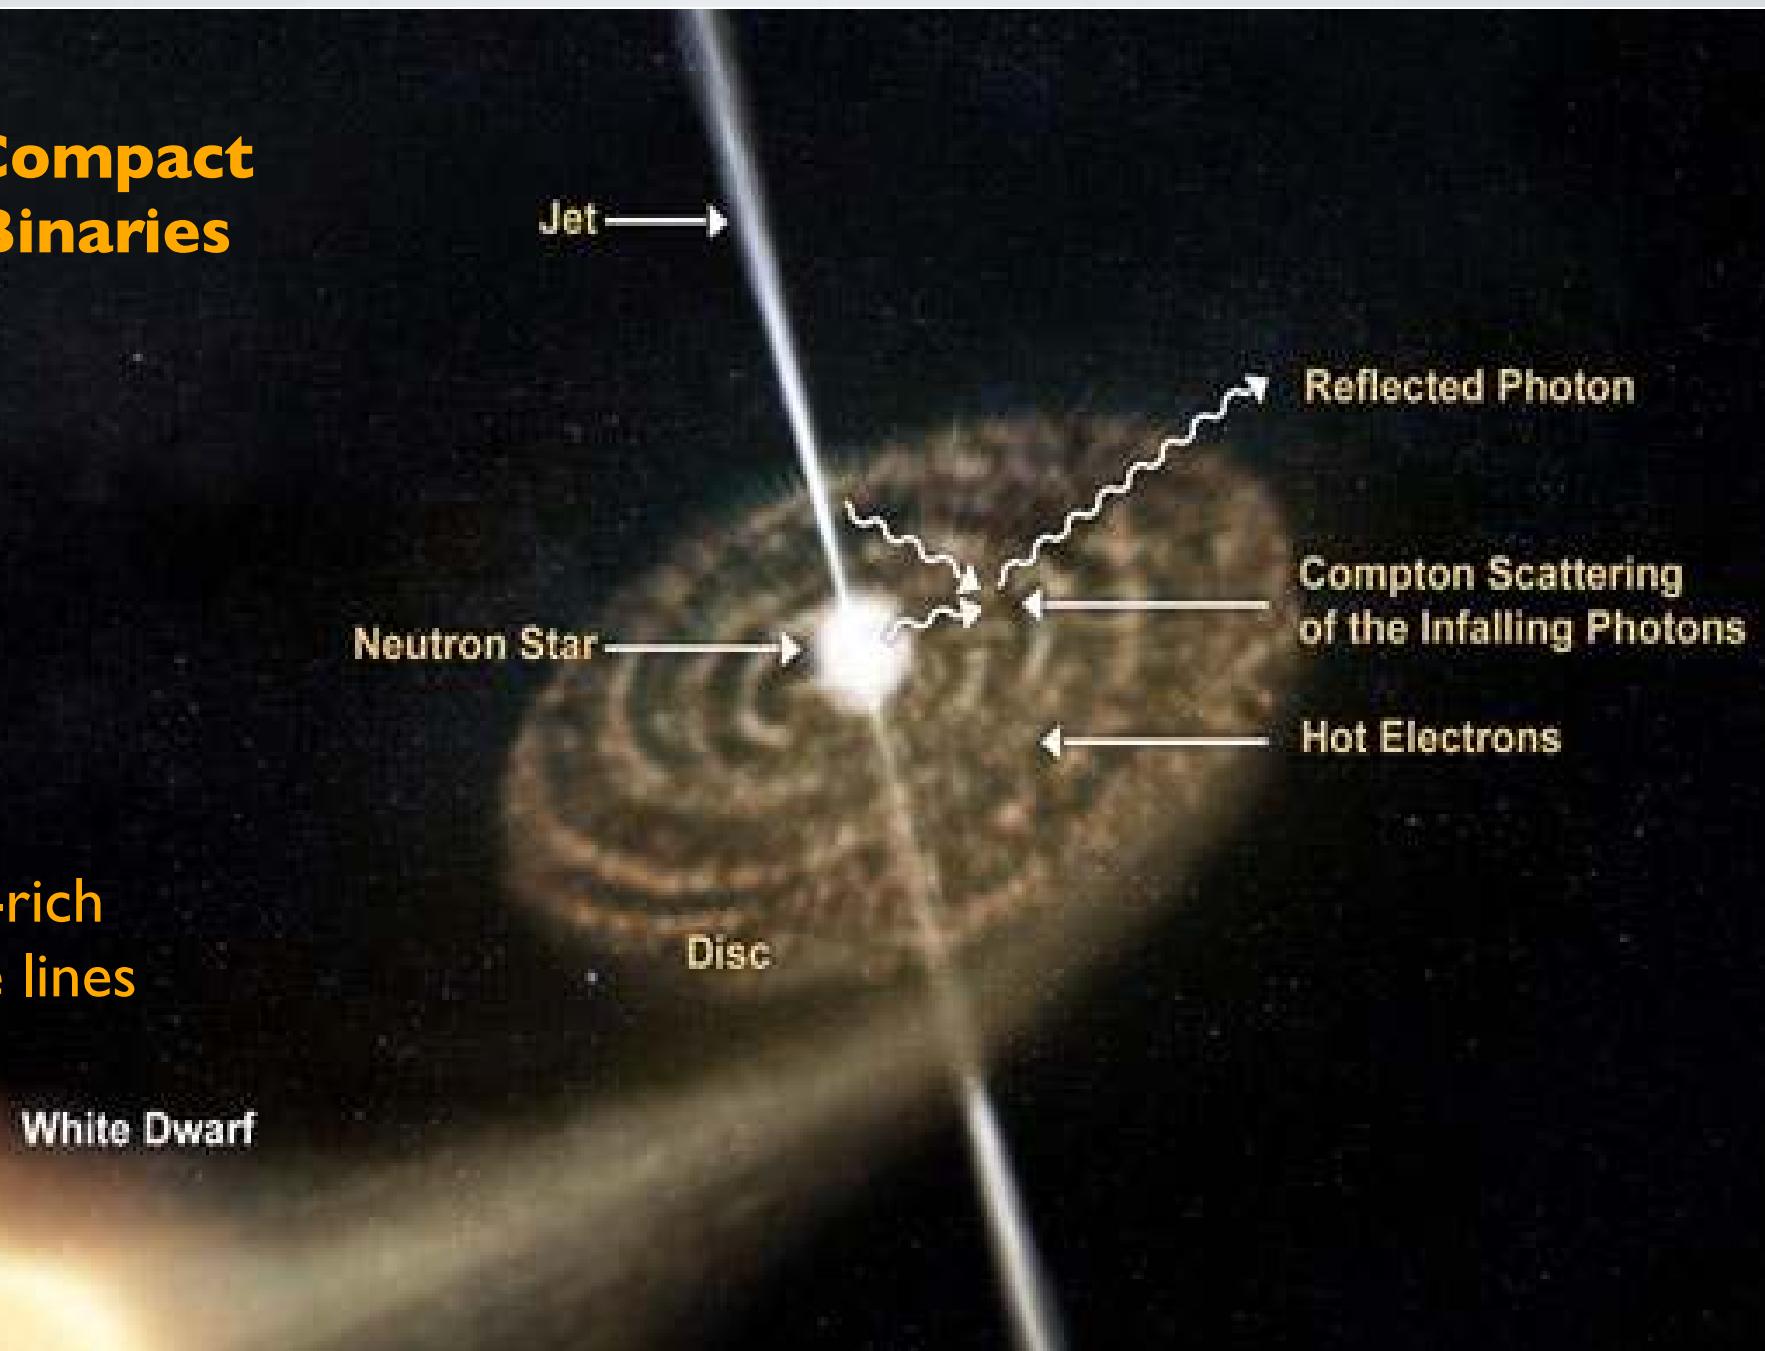

Iron K lines in three Neutron Stars observed with Suzaku (Cackett et al. 2008)

In this case, the Fe K-line provides an estimation of the NS radius, which together with the mass constraints the eq. of state.

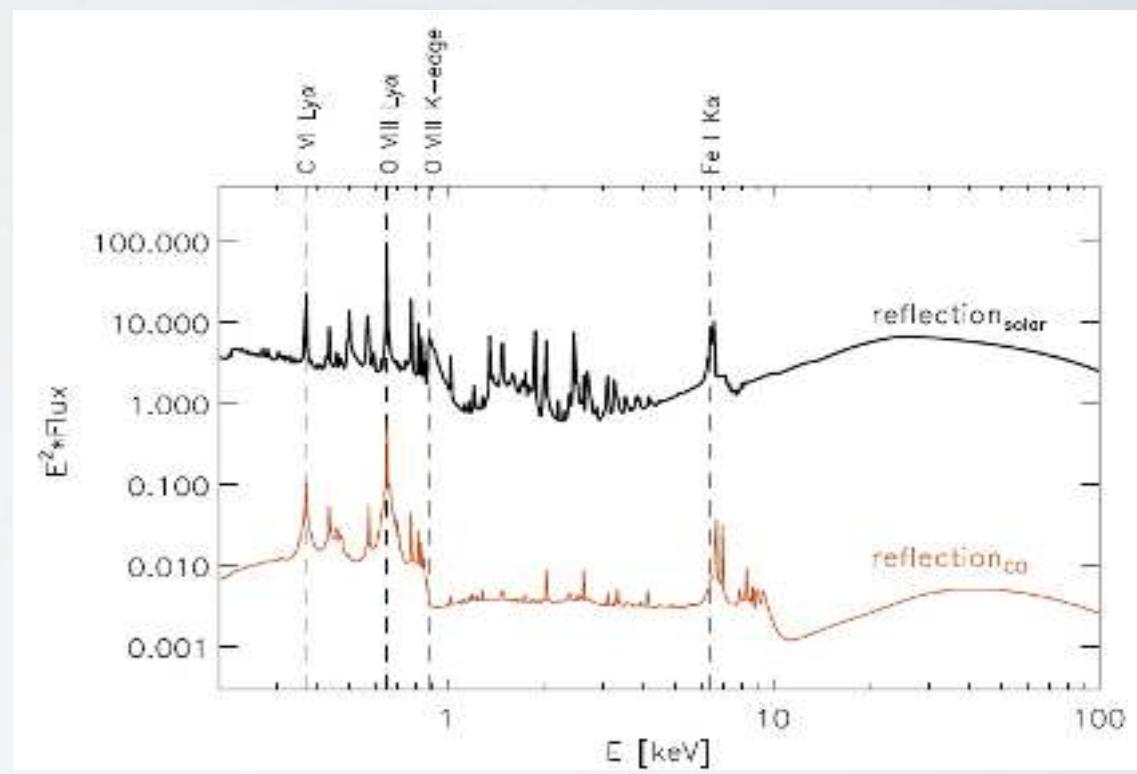

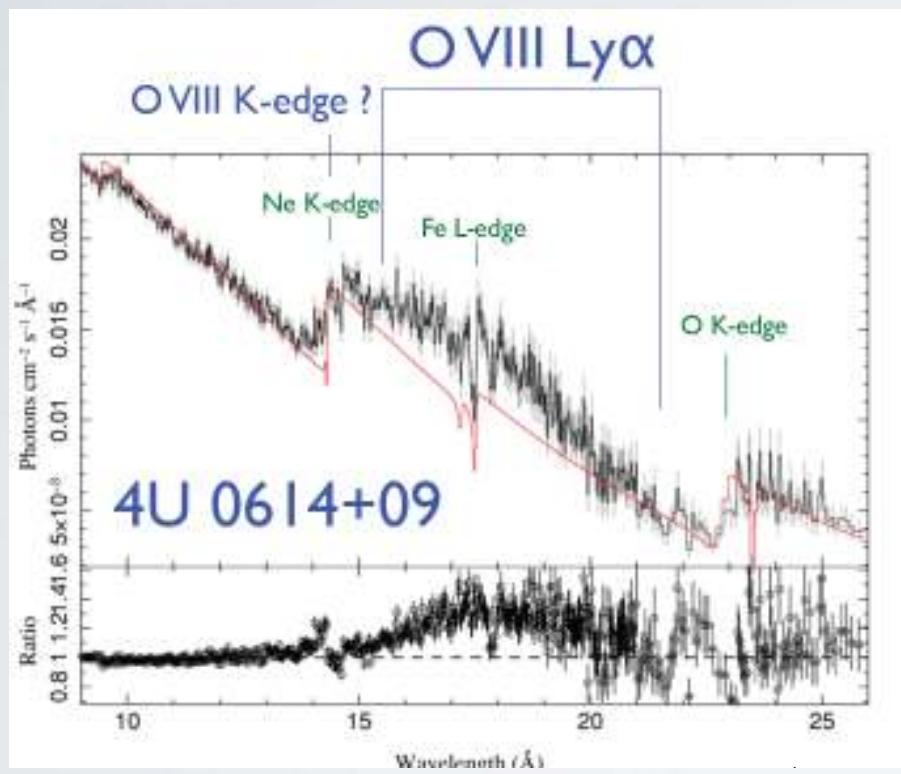

# Relativistically Blurred Oxygen?

**Ultra-Compact  
X-ray Binaries**

# Relativistically Blurred Oxygen?

4U 0614+09: Neutron star with a Carbon and Oxygen rich White Dwarf donor.

Chandra spectra shows strong O VIII Ly-alpha emission.

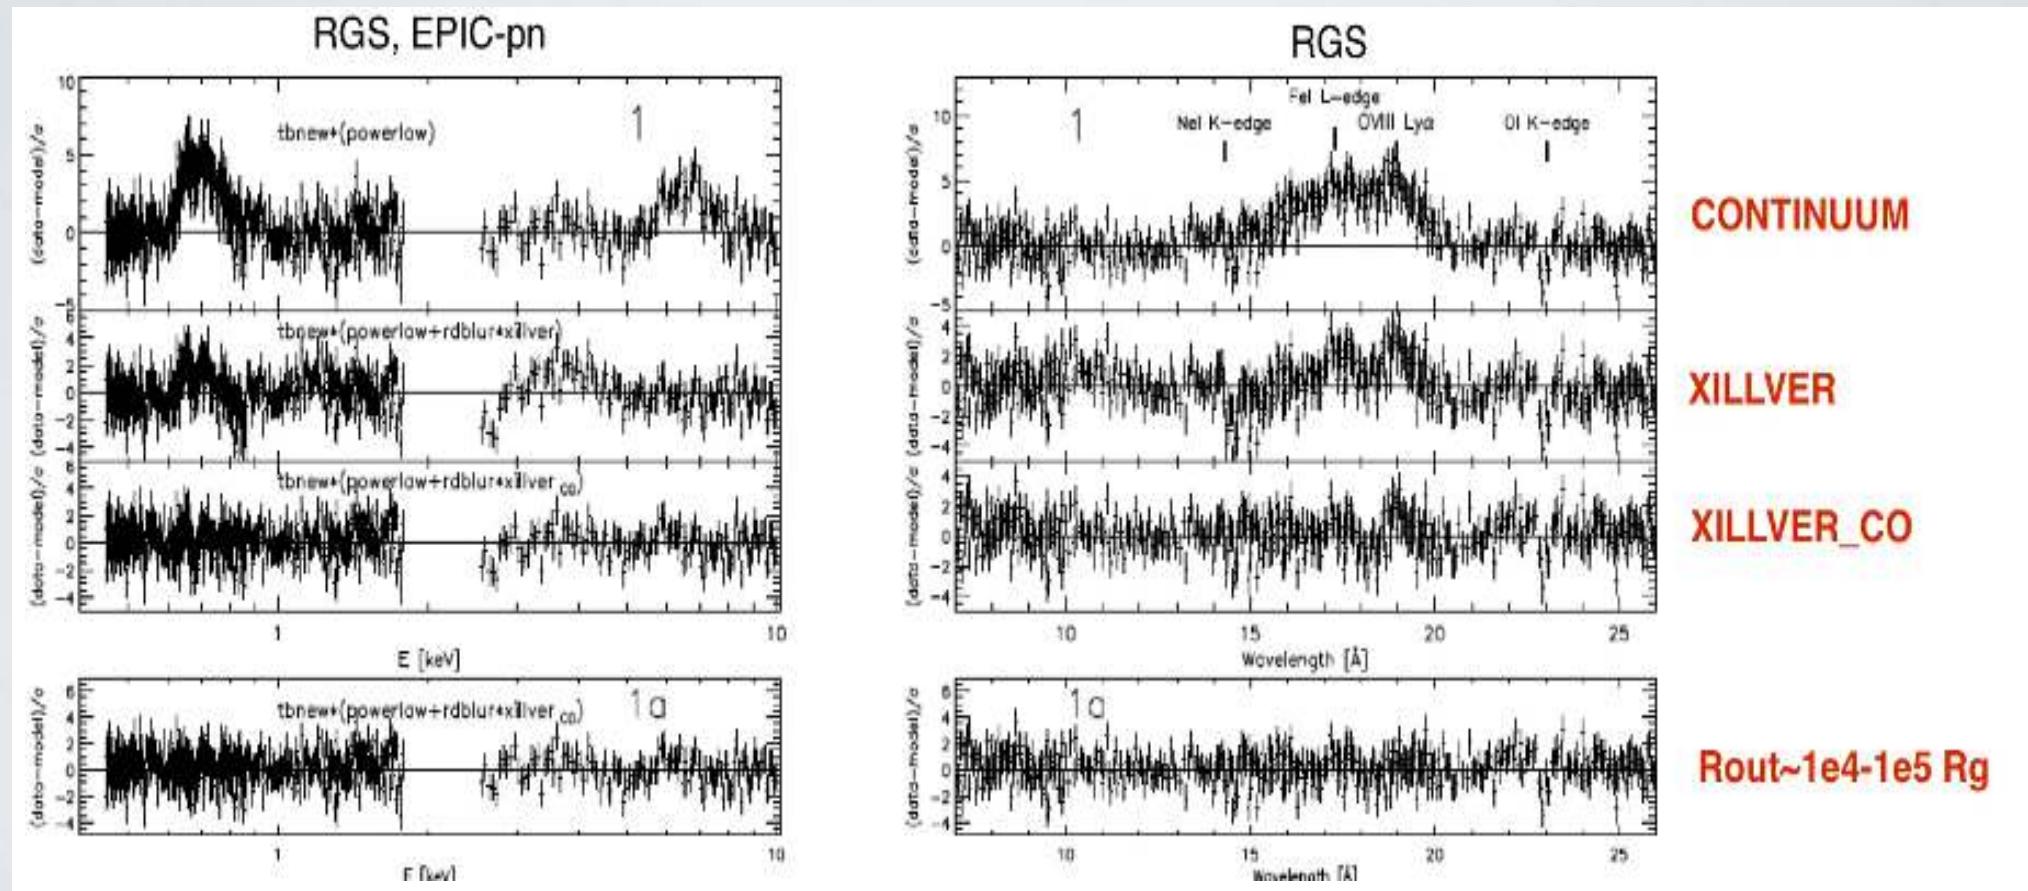

Custom-made XILLVER model with low H & He abundances (1% solar)

C & O abundances are free parameters

# Fits to 4U 0614+091 XMM Data

C & O Abundance:  $140 \pm 50 \times$  Solar value

Strong Ne K-edge or OVIII K-edge? No neon emission in optical spectra

Madej, Garcia et al. (2014)

# Summary

---

**X-ray Reflection Spectroscopy** provides one of the most powerful tools to study accreting black holes, with which one can study:

- \* **The Evolution of Disk and Corona:** changes in the corona and accretion disk appear to be correlated. This indicates a connection in the physics that governs the evolution of both structures.
- \* **The Spins of Black Holes:** Estimates of BH spins for both AGN and BHB are important to understand their formation and evolution history.
- \* **The Physics of the accreting flow:** Large iron abundances in reflection measurements are indicative of high-density plasma effects, likely affecting the atomic structure properties.

# Escuela Latinoamericana de Relatividad y Astrofísica (ELRA)

---

Diciembre 1-3, Online

Esta pequeña escuela tiene como objetivo ofrecer cursos introductorios a estudiantes de habla hispana. Los cursos proporcionarán las herramientas más básicas necesarias para iniciarse en la investigación de algunos temas actuales en astrofísica relativista.

La inscripción será gratuita y abierta a toda la región.

Cursos (Sesiones de 45+15)

- \* **Física de Objetos Compactos (Jorge Rueda (ICRANet))**
- \* **Técnicas estadísticas para el análisis de datos astrofísicos (Cecilia Garraffo (Harvard) )**
- \* **Técnicas de análisis espectral en rayos X de objetos compactos (Mariano Mendez (Groningen))**

Comité organizador:

Alejandro Cárdenas-Avendaño (Fundación Universitaria Konrad Lorenz/ Princeton University)

Javier García (California Institute of Technology)

Luis Nuñez (Chair, Universidad Industrial de Santander)

Jorge Rueda (International Center for Relativistic Astrophysics)

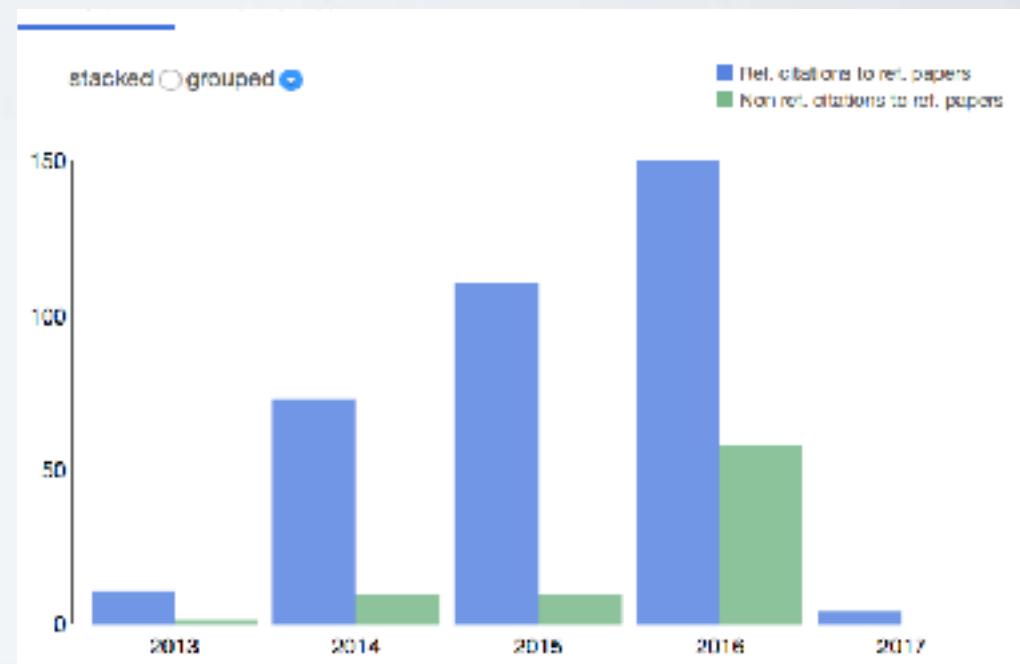

# Adicionales

---

# Some Reflections

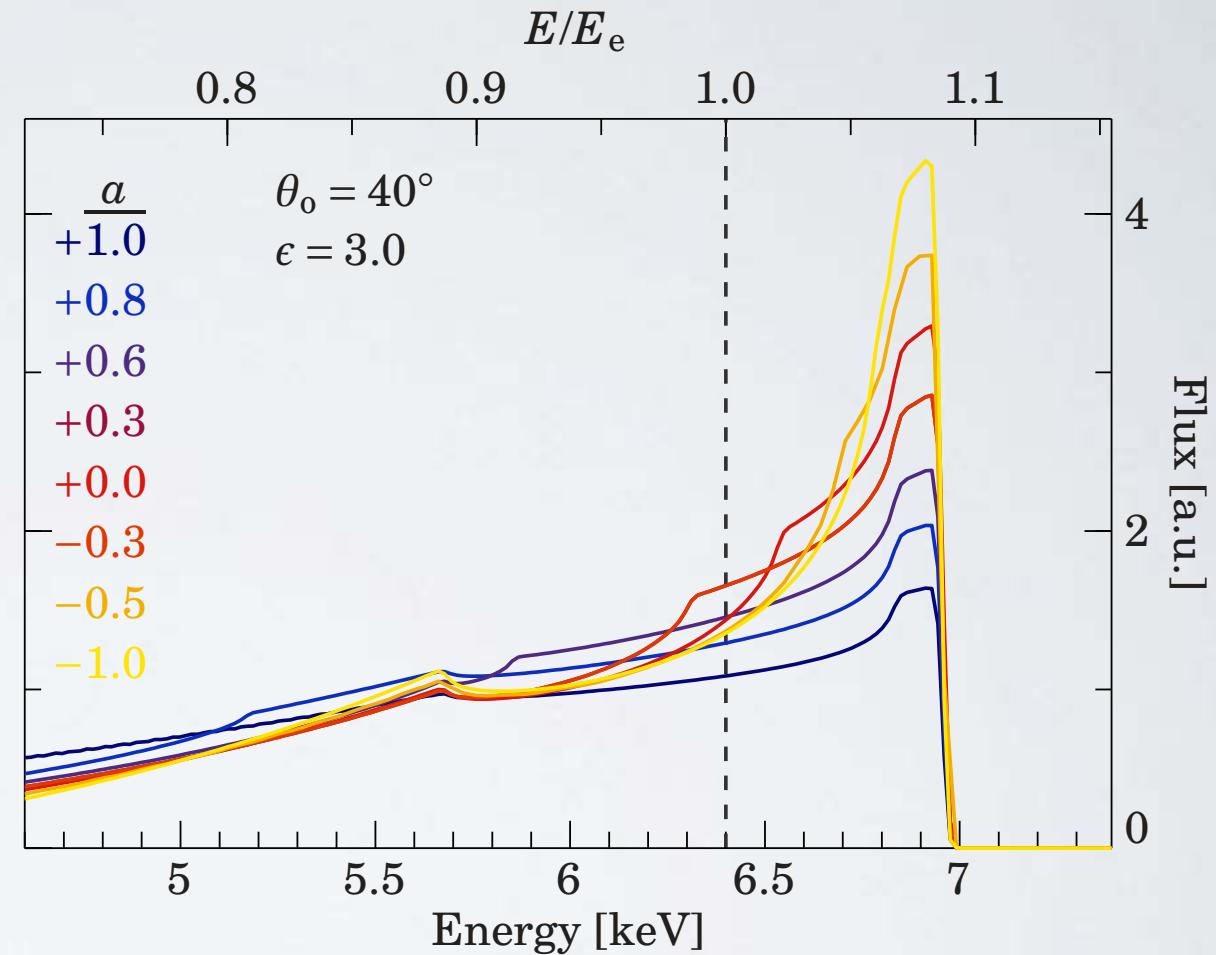

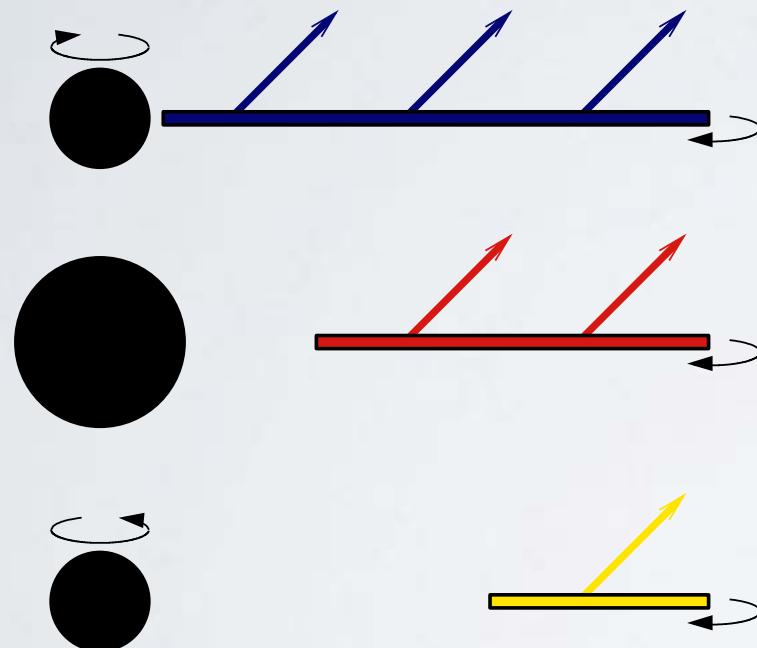

- Reflection spectroscopy has proven to be a fantastic tool to study the inner-most regions of accreting sources.
- The state-of-the-art atomic data and modeling tools are allowing us to impose tight constraints on important parameters such as spin, inclination, and Fe abundance.
- The community has played an important role in the improvement of our models:
- 180 Citing papers
- ~120-140 fits to a single source
- Most of these (~80) are NuSTAR observations!

*All of physics is either impossible or trivial. It is impossible until you understand it, and then it becomes trivial.* —Ernest Rutherford

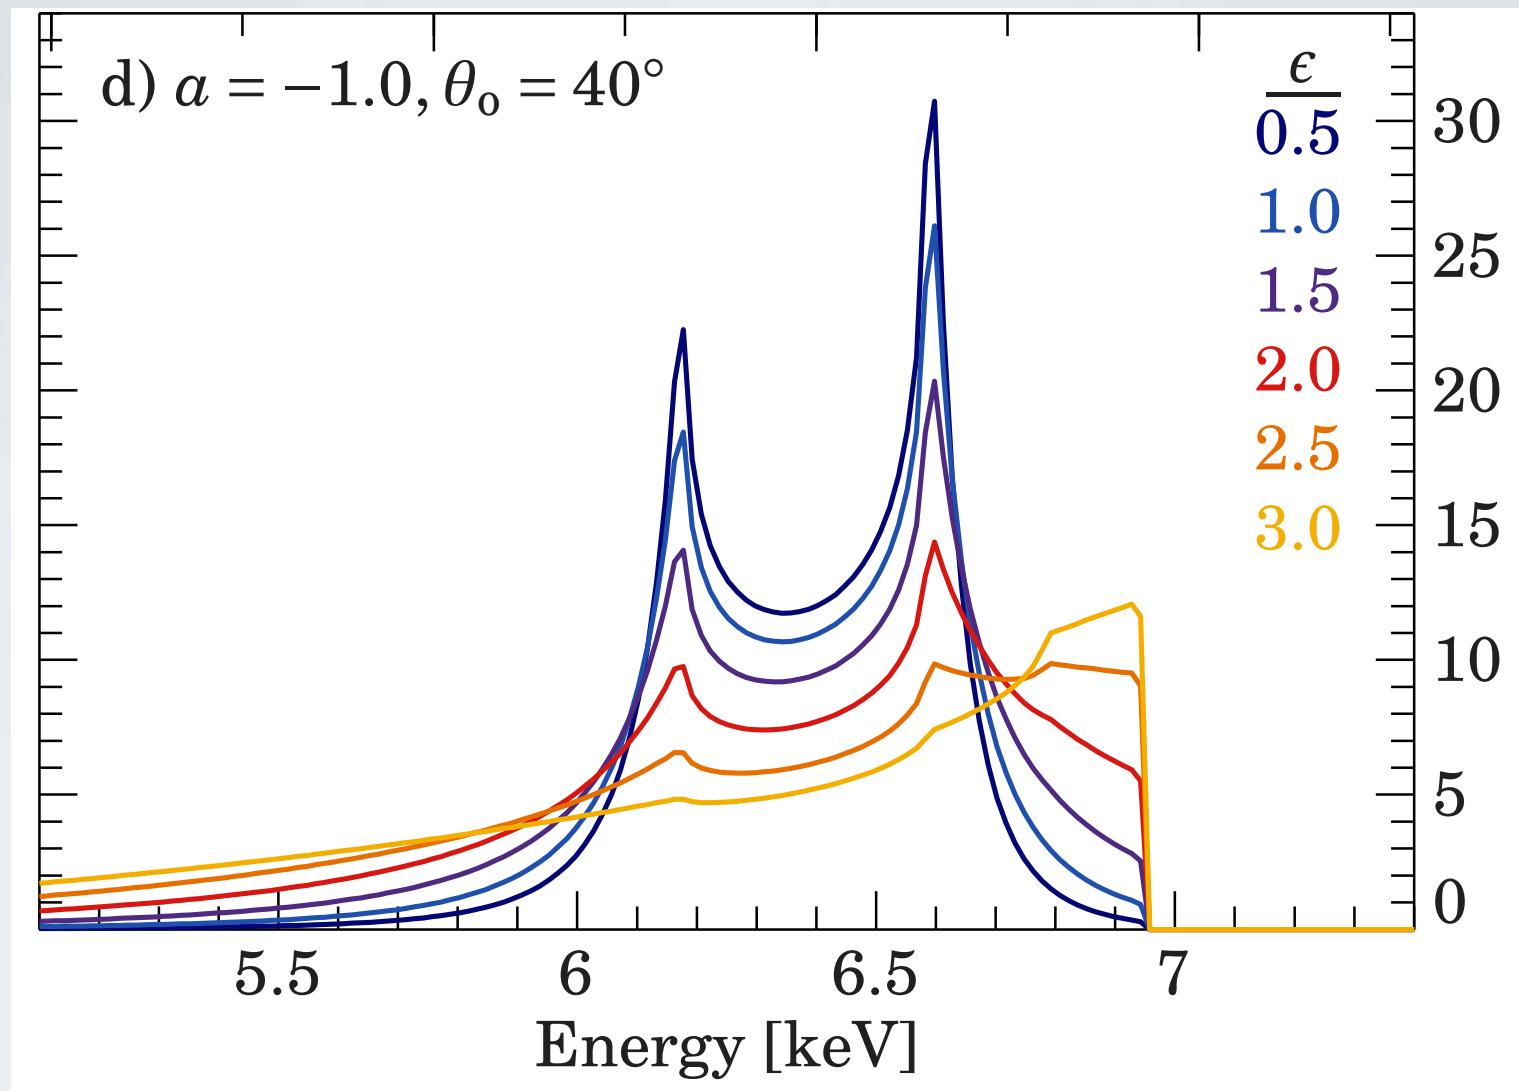

# Diagnostic Tool: Black Hole Spin

possible **Spin** values:  $a = -1 \dots 1$

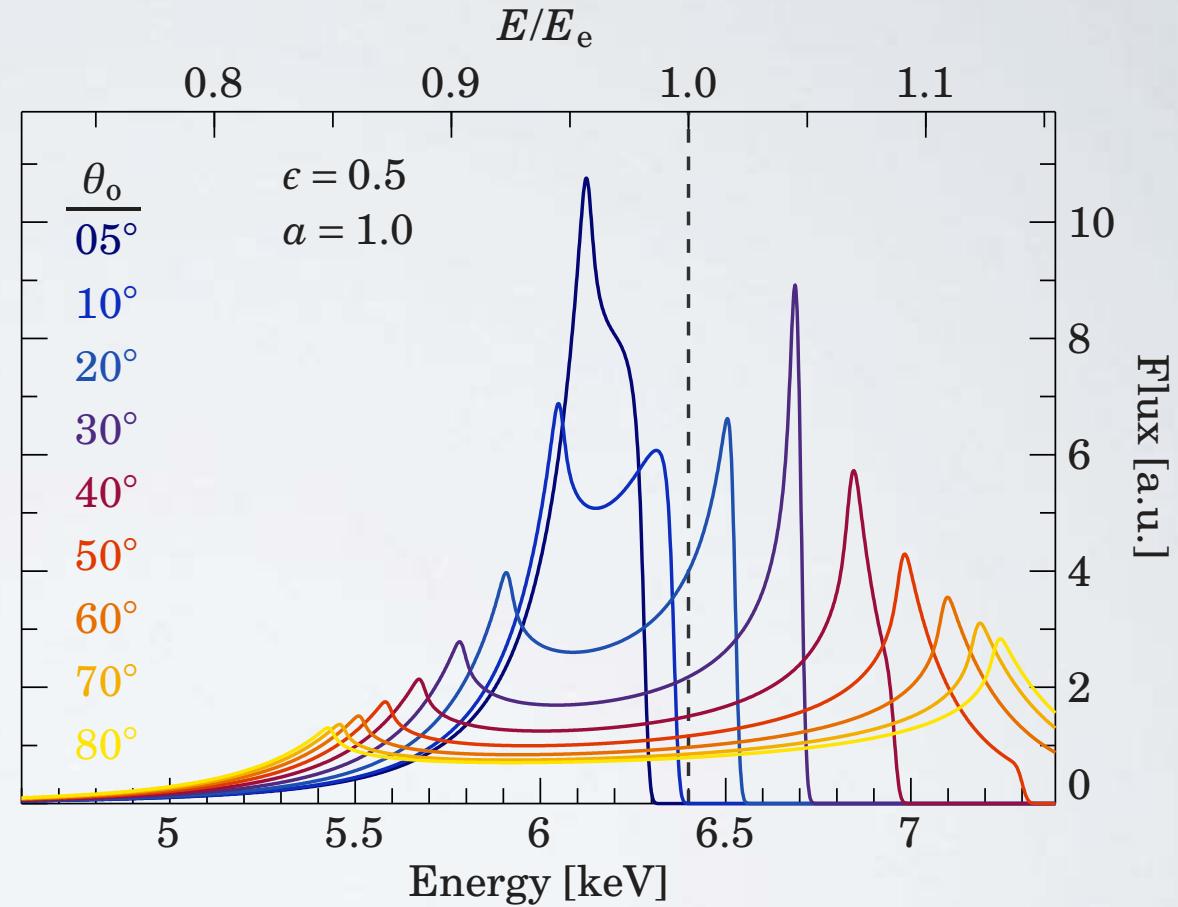

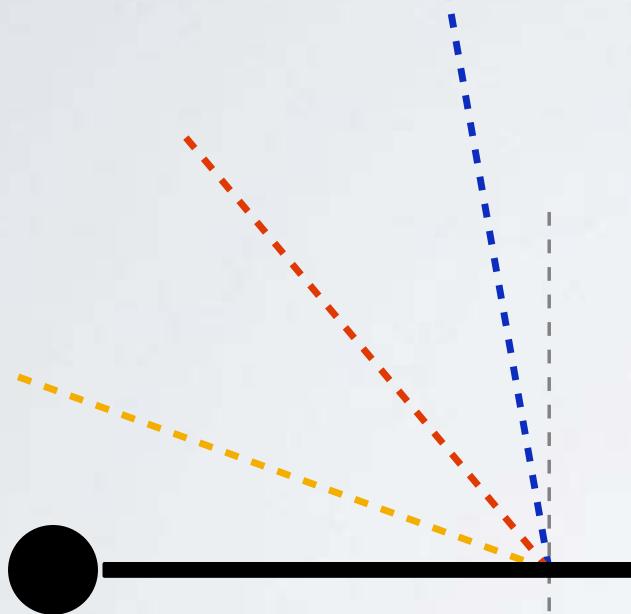

$a = cJ/GM^2$  (Dimensionless Spin Parameter)

# Diagnostic Tool: Emissivity Index

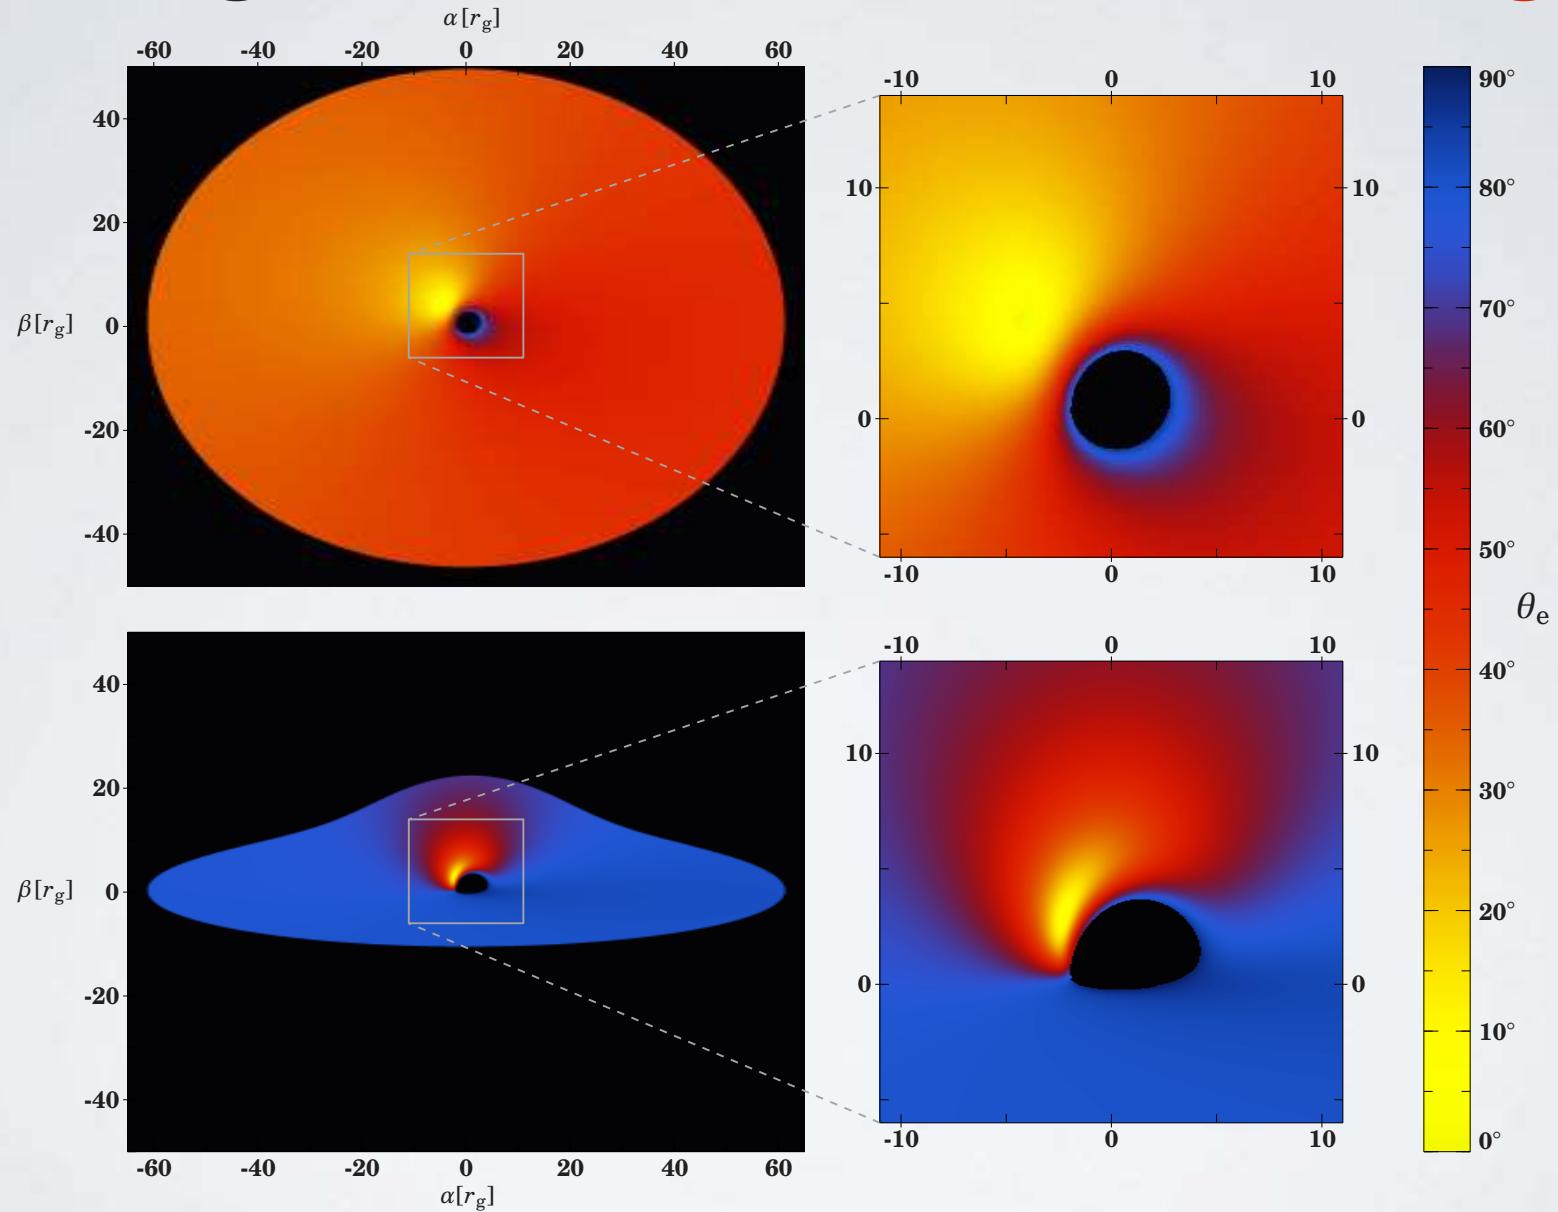

Assumes illumination (and thus emission) follows  $F \sim r^e$

# Diagnostic Tool: Inclination

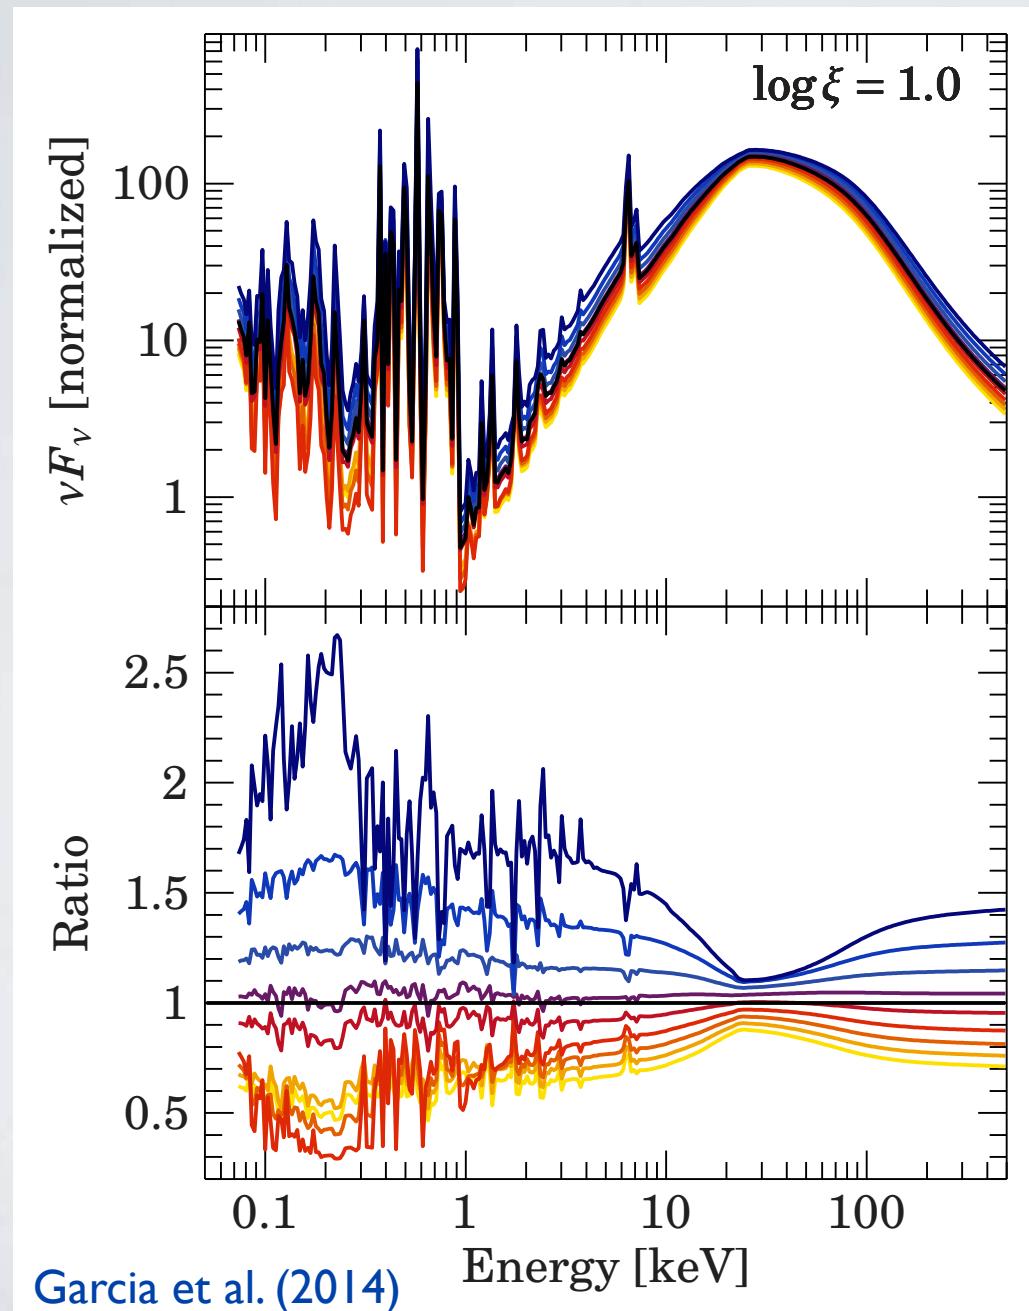

Inclination mostly affects the blue side of the line

# Diagnostic Tool: Emission Angle

Garcia et al. (2014)

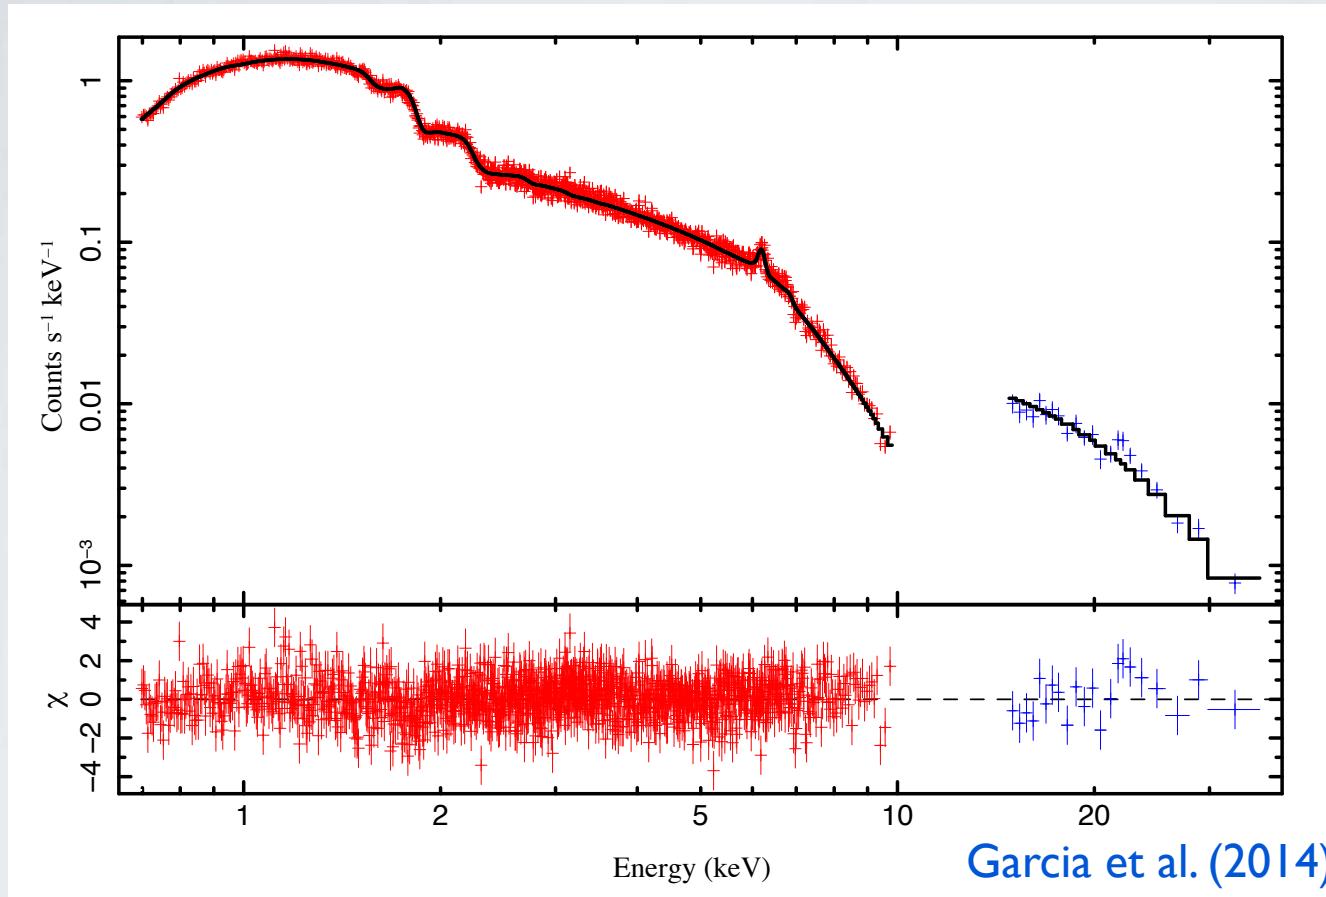

# RELXILL: The Emission Angle

The reflection spectra  
differ depending on the  
Emission Angle

Previous convolution  
models use Angle  
Average Spectra

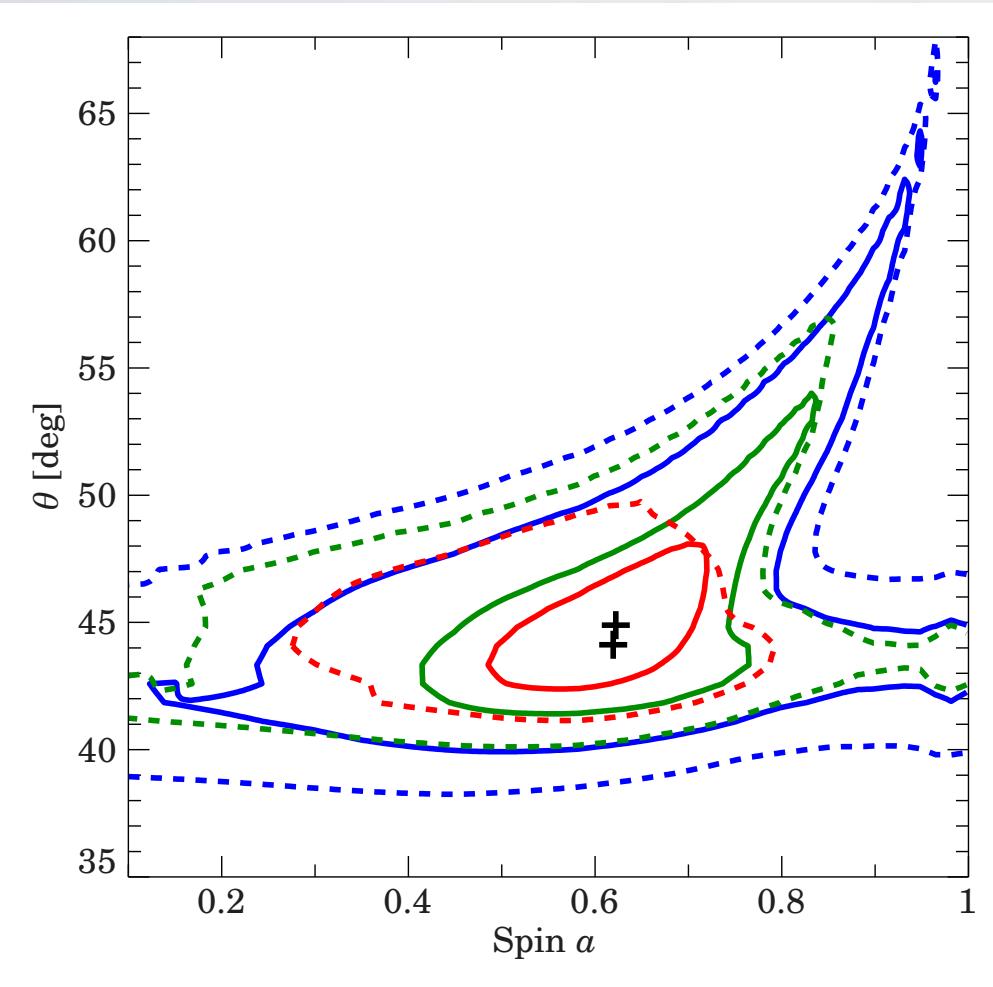

# RELXILL: Fits to Ark 120

Par	Value
$q_{in} = q_{out}$	$4.8^{+1.8}_{-1.1}$
$a$	$0.655^{+0.122}_{-0.126}$
$i$ (deg)	$45.3^{+4.8}_{-2.4}$
$R_{in}$ (ISCO)	1
$R_{out}$ (ISCO)	400
$z$	0.0327
$\Gamma$	$2.17^{+0.02}_{-0.01}$
$\log \xi$	$0.84^{+0.24}_{-0.10}$

angle_on	1
$N(10^{-4})$	$2.07^{+0.2}_{-0.2}$
$N(10^{-4})$	$0.14^{+0.07}_{-0.04}$

Suzaku spectrum of the Seyfert I galaxy Ark 120. Solid line is the best fit model with RELXILL.

# RELXILL: Fits to Ark 120

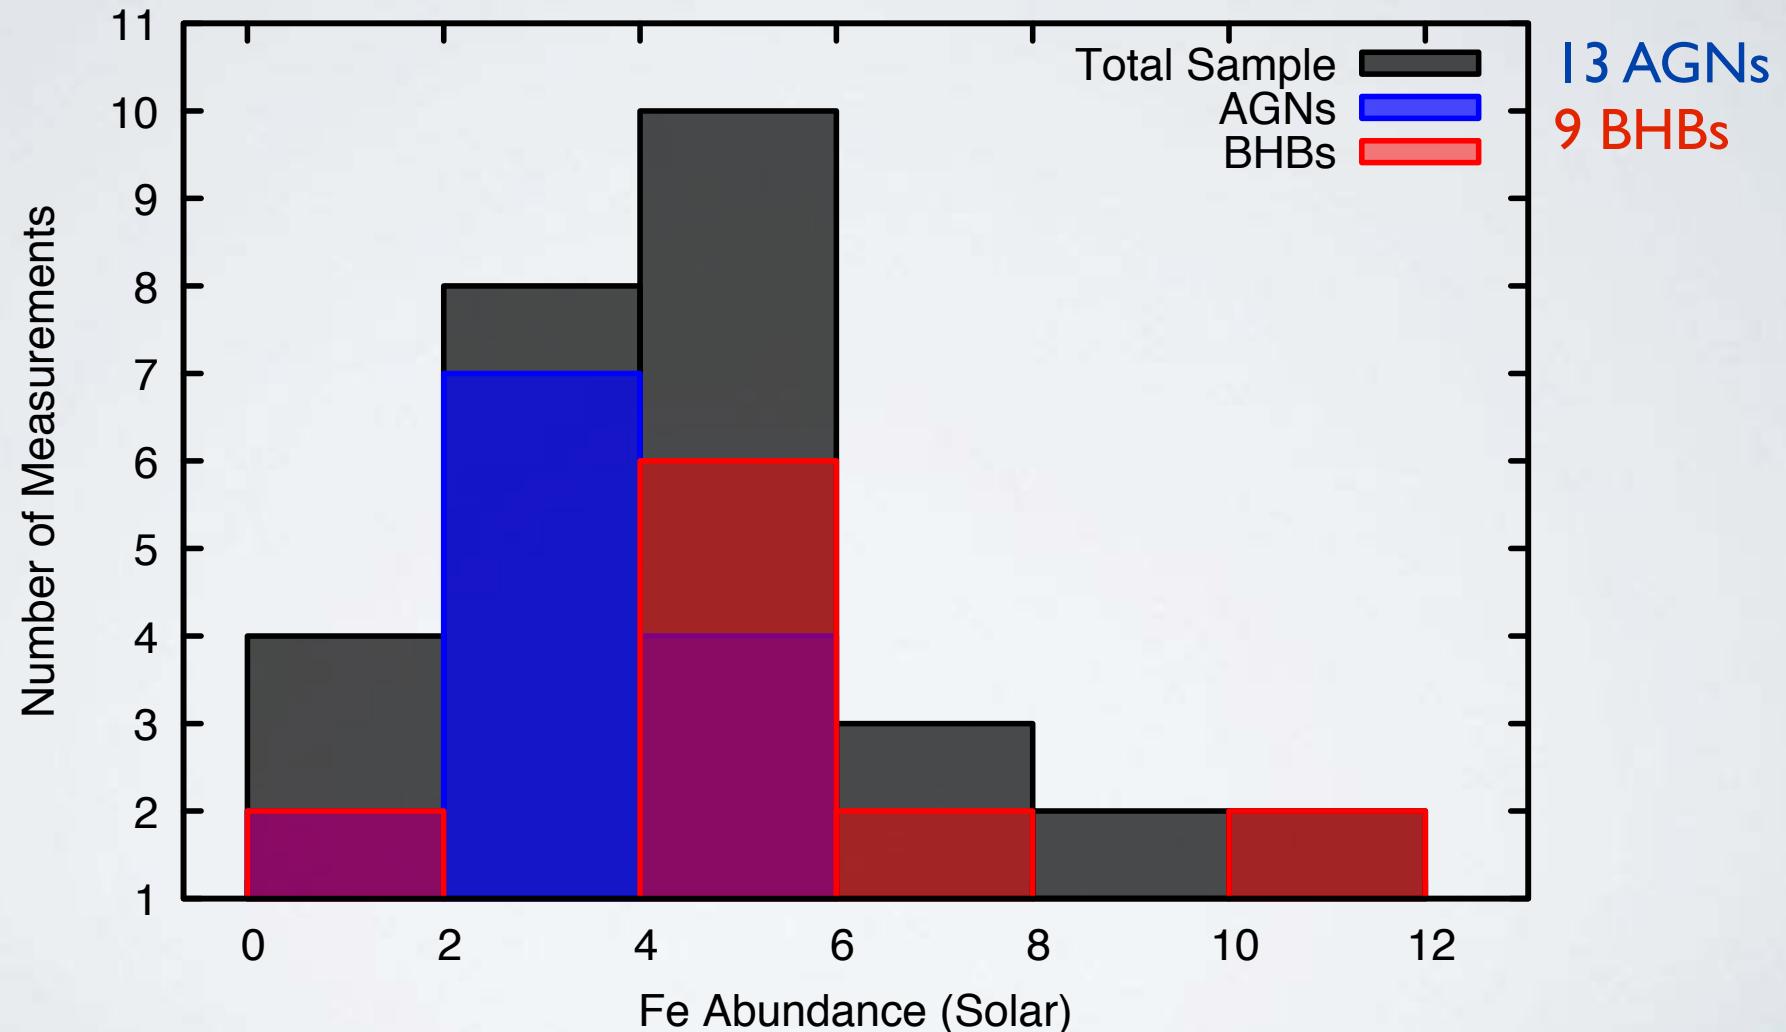

Contours plots of  
inclination and spin for  
69%, 90% and 99%  
confidence

The uncertainties are dramatically reduced when the angle-resolved model (solid lines) is implemented.

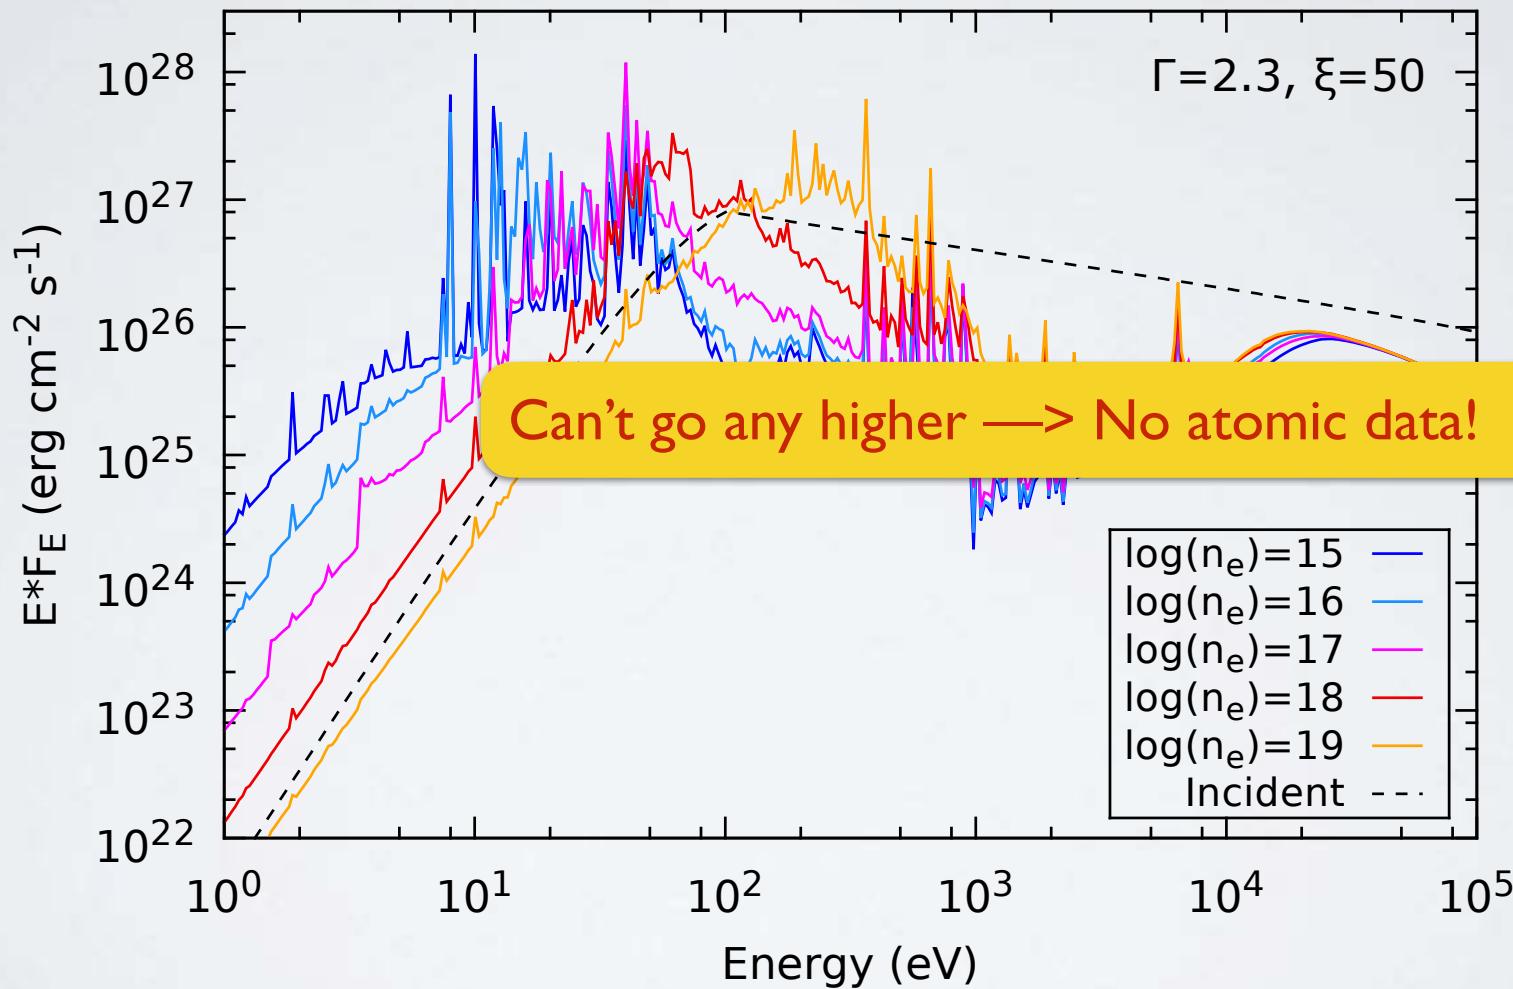

# The Problem of the Iron Abundance

Iron abundance determinations using reflection spectroscopy from publications since 2014 tend to find a few times the Solar value!

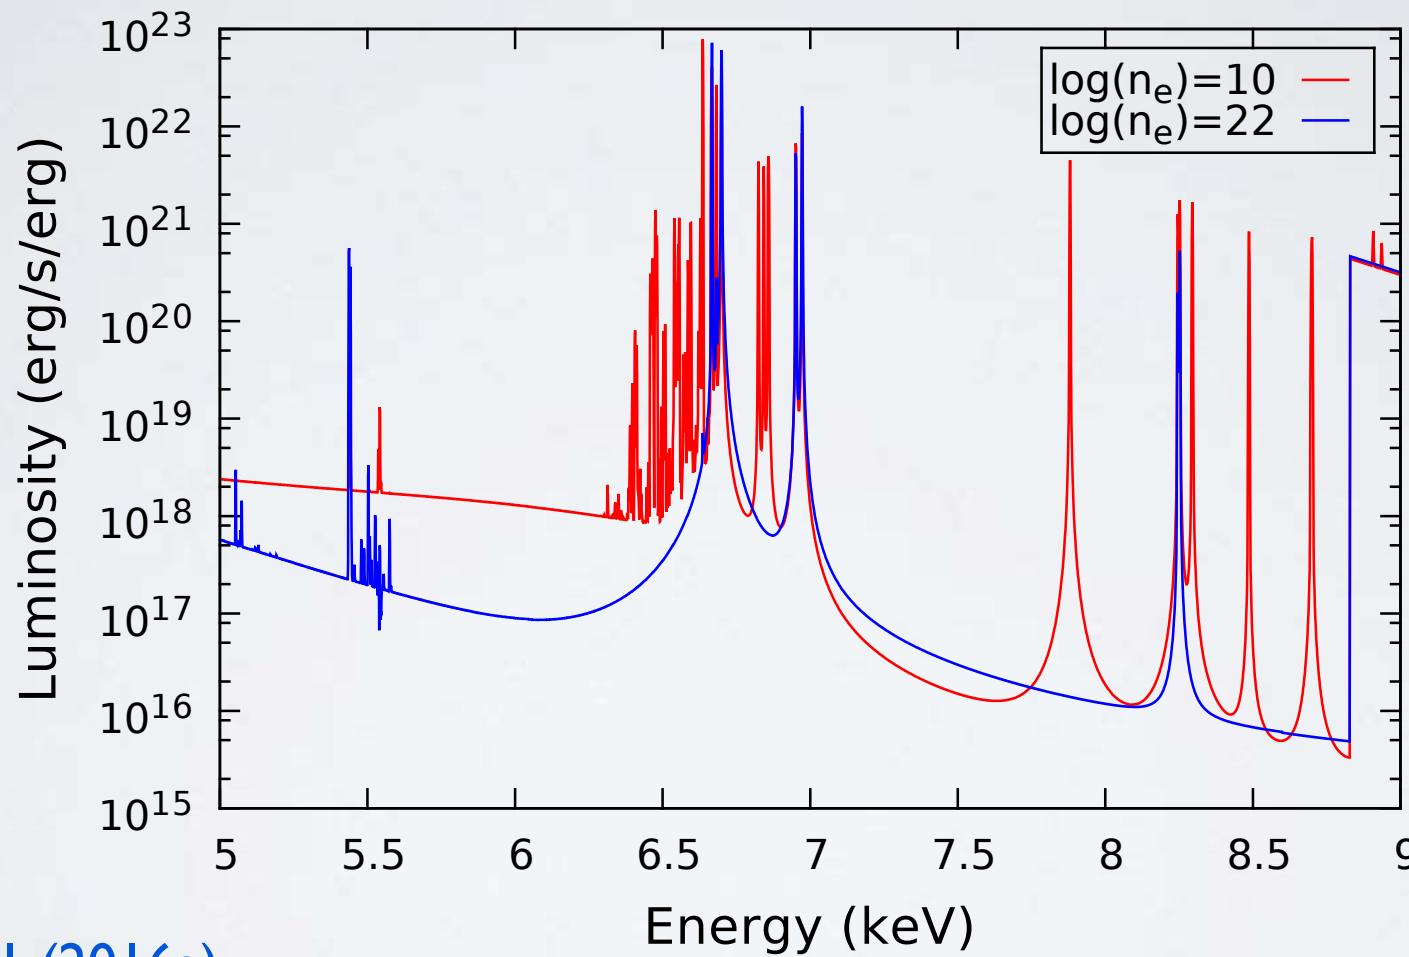

# High-Density Effects

Models with high gas density ( $n_e \gg 10^{15} \text{ cm}^{-3}$ ) produce a remarkable flux excess at soft energies as **free-free emission becomes important**.

# High-Density Effects

High-density effects such as continuum lowering could have an impact in the Fe abundance. However, new atomic data for high density plasmas is required!

García et al. (2016a)

# The Hardness-Intensity Diagram
